Slit, Argand, incandescent, and inverted regenerative burners were included in the tests, which were conducted in such a manner as to determine the light-giving power of the burners with variable consumption of gas, in order to ascertain the favourable conditions of combustion for each of them. Measurements of the quantities of gas employed were made by means of an experimental gas-meter, which indicated the actual consumption of gas in litres. With the smaller burners, the consumption was observed during 5 minutes; with the larger ones during 15 minutes. Photometric measurements were carried out with a Bunsen photometer made by Herr Elster, of Berlin; an angle photometer being employed for the inverted regenerative burners. A normal burner from the same factory served in most cases as the standard; but for the regenerative burners an Elster Argand with adjustable air supply was used.* The ordinary Argand was compared every evening with an English standard candle; the height of the flame being 45 mm. With a consumption of 150 litres (5·30 cubic feet) per hour, the intensity of the Argand burner fluctuated between 14·5 and 14·75 standard candles. The gas was also thoroughly tested with Sugg's "London" Argand burner, and with the Paris standard burner of Bengel; n-ing in each case the prescribed quantity of gas—viz., with the Sugg burner, 141·6 litres (5 cubic feet) = 16 candles in London; with the Bengel burner, 105·0 litres (3·71 cubic feet) = 1 Carcel, or 9·6 candles in Paris; and with the Elster burner, 150 litres (5·3 cubic feet) = 17 candles in Berlin. The present results may therefore be compared with others obtained with these burners with different gas. The specific gravity of the St. Petersburg gas varies from 0·37 to 0·45 at 15° C. In the original communication, the quantities of gas consumed are given both in litres and cubic feet, and consequently the results are of universal utility. To facilitate comparisons of the efficiency of individual burners from an economical point of view, the gas consumed per hour and candle, and the number of candles corresponding to the consumption of a definite volume of gas, are given in each case.

Slit Burners.

No.	Name of Burner.	Gas Consumption per Hour in Cub. Ft.	Illum. Power in Standard Candles.	Gas Consumption per Candle Power per Hour in Cub. Ft.	Candle Power per Cub. Foot.

		6·50	11·75	0·55	1·81

All the slit burners were hollow topped. In these experiments the plane of the flame was parallel with that of the photometer screen. In some experiments with the plane of the flame at right angles to that of the screen, a lower illuminating power was obtained. For example, burner No. 1, with the gas consumption shown in the table, gave, when parallel, 16, 21, and 27 standard candles, while at right angles it indicated only 14·5, 16·5, and 23 candles. The table shows that the consumption of gas for different slit-burners averages 0·44 to 0·55 cubic foot per candle per hour, or that 1 cubic foot of gas gives the light of from 1·81 to 2·25 normal candles.

* The efficiency of a new burner or high-power lamp is now generally tested by comparing it with a standard light on a specially constructed photometer, whilst the illuminating power of the gas itself is either determined by means of a separate ordinary photometer or not determined at all. In the new gas-works at Rotterdam, the unavoidable errors attached to these modes of procedure are eliminated by the use of an ordinary flame of 16 candles as the standard of light in the special photometer, with which the gas itself may then at any time be tested.

The results with Argand burners were as follows :—

		8·34	31·4	0·26	3·75

Burners Nos. 11 to 18 had discs—No. 11 a porcelain one, the others of metal. The Siemens "Precision" burner, and Rotsiper's burner with arrangement for heating the air supply (Nos. 17 and 18) in the above table, were the most complicated; but they show a greater saving of gas than the ordinary Argand burners. From these results it may be assumed that, on the average, Argand burners consume from 0·32 to 0·53 cubic foot of gas per candle per hour; and for each cubic foot consumed give from 1·83 to 3·13 candles' light.

Only two kinds of incandescent burners were tested—the Lewis-Sellon, with platinum cone, and the Welsbach. The latter gave a whiter and more agreeable light than the former. The results show that altogether these incandescent burners do not effect any greater saving of gas than the Argand burner. They, however, do not burn as steadily.

		11·78	55·1	0·22	4·68
		15·62	99·2	0·16	6·35
28	Do., No. 3.	15·17	48·3	0·31	3·18
		17·29	86·3	0·20	5·02

Passing on to inverted regenerative burners, they were all, with the exception of the small "Cromartie" burner, which was only tested at an angle of 45°, tried at angles of 30°, 45°, 60°, and 75°. The following results with Butzke's burners, with a consumption of gas of 15·85 cubic feet per hour, are given as an example of the variation in intensity with the angle:—

Angles	30°	45°	60°	75°
Standard candles	80·5	84·2	95·2	104·3

For the sake of brevity, only the mean of the four measurements is given in the preceding table.

A comparison of these burners as regards their consumption of gas indicates a great economy with the more powerful ones, except in the case of the horizontal flat-flame burner, which, with the small consumption of 6·47 cubic feet of gas, yields the high illuminating power of 40·1 candles, which is equal to 1 candle for a consumption of 0·16 cubic foot per hour—a performance only attained by the other burners with a much larger consumption of gas.

Comparing the smallest consumption per candle per hour for the different types of burners, it will be seen that, under the most favourable conditions of burning, slit burners consume 0·44, Argand burners 0·32, and regenerative burners 0·15 cubic foot; therefore in this particular they stand in the relation of 3:2:1. So that, as regards the consumption of gas, regenerative burners are three times as economical as slit burners, and nearly twice as economical as Argand burners. But, of course, the initial cost and the working expenses must also be taken into consideration.

THE DETECTION OF LEAKS IN WATER-MAINS.

In Vol. XC. of the "Proceedings of the Institution of Civil Engineers," the Engineers of four of the London Water Companies (Mr. J. Francis, of the New River; Mr. W. B. Bryan, of the East London; Mr. A. Fraser, of the Grand Junction; and Mr. J. W. Restler, of the Southwark and Vauxhall) contribute some interesting notes on the detection of leaks in water-mains.

Dealing first with the New River Company we find that the pipes generally lie in clay, and the water escaping from any defective place is at once directed towards the surface. Even where the stratum is gravel, it is usually of so compact and loamy a nature that the effect is practically the same. A leak, therefore, most frequently shows itself immediately over the weak place, even though there may be concrete and asphalt above, the water having a tendency to filter through the concrete, and to force up the asphalt covering in the form of a blister. Occasionally, however, it is first seen at some distance, having crept along the side of the pipe to a place where the filling-in above may happen to be loose, or of a nature more easily penetrated. Or it may travel along the under side of the paving until some point is reached where the continuity of the outer skin is broken—as at a kerb, a gully, or in front of a house. In such cases the leak is found by digging down at the various pipe-joints until the right one is discovered. Where there happens to be a sewer in close proximity, the water may find its way in, and thus attract attention. Undoubtedly, an impermeable surface to a road greatly increases both the difficulty of localizing a leak in an underground pipe, and also the extent of damage that is likely to occur before the evil can be remedied. A successful method of following a leak having an underground exit has been to remove a small portion of the surface covering in several places near the suspected spot, and to bore down to the required depth with an auger of 2 or 3 inches diameter. The escaping water has necessarily a certain amount of fall from its point of origin, and consequently stands highest in the hole nearest to that point. By boring further holes in the direction indicated, the site of the leak is at length reached. With regard to the arrangement of the pipes in streets covered with concrete, the New River Company do not spare any pains to ensure that the iron may lie on a solid bed, and the joints be soundly made; but further than this no special arrangements are provided for detecting any leakage that may occur.

With regard to the East London Water-Works Company, we are told that where asphalt or wood pavement is laid, leaks in water-mains are exceedingly difficult to localize. In some cases, the water, being unable to rise to the surface, makes its way into a basement which may be at a considerable distance from the actual leak; in other cases, the water will force up the pavement in the weakest place in the neighbourhood. The ground is then opened, and the leakage has to be traced to the fractured pipe, to the great cost of the Company and inconvenience of the public. In the Company's district there are comparatively few roadways of wood or asphalt, and these are principally situate in the City. Where ordinary pavements are upon a clay foundation, leaks show almost exactly over the fractured or faulty pipes. In the neighbourhoods of Bow and Old Ford, and many other places in the East-end, the subsoil is gravel, and leaks do not always show on the surface, as the water passes away without detection into deep sewers and elsewhere. In these cases leaks are difficult to localize. If the supply to the houses near is insufficient, the cause is sought, and sometimes a length of pipe has to be uncovered to detect the fault. The East London Company use Deacon's waste-water meters; and they also "stethoscope" the pipes at various places. These methods frequently enable the leaks to be localized. In this Company's district the pipes were mostly laid anterior to the introduction of concrete pavement—no special arrangements having been made. But great care is exercised in jointing the pipes, which are run with lead. A novel system has been introduced for detecting leaks on a particular service, which so far has proved more successful than anything else. It is simply the

employment of a small bye-pass of $\frac{1}{2}$ or $\frac{3}{4}$ inch diameter, spanning an ordinary sluice-cock. The sluice-cock on the service pipe (supplying 50 houses, more or less, and in some cases 100 houses) is shut, and the bye-pass opened. It is known how much water will go through the bye-pass, and that it is sufficient for all the needs of the consumers. If complaints of insufficient supply are made, it is evident there must be either waste or leakage; and a visitation is made to all the houses. If the fittings are good, there must be a leak somewhere; and the site can generally be ascertained by listening at various points, or boring with an auger.

In the district of the Grand Junction Water Company there are but few streets laid with asphalt; and there are no subways. Until recently the streets were paved with granite setts laid on concrete or gravel, or with broken granite (macadam), or simply with gravel. In either case, when a leak occurs it soon asserts itself on the surface; and the exact site is readily found. Moreover, the escaping water runs down the gutters and gratings into the sewers. Now, however, the practice is to take up all the macadam, and mix it with Portland cement into a concrete, which is spread evenly over the whole surface of the road about 6 inches thick. On this wood blocks are laid. The substratum of the greater part of this Company's district is clay; but it is traversed by sewers and drains. Most of the houses have basements, and also cellars under the pavements. Consequently when a pipe bursts, or a leak occurs, the water finds an impermeable ceiling above, and the pressure drives it either into the sewer or into some basement or cellar, whichever may be nearest. Great trouble and expense result, as the Company usually compensate those who receive injury. Moreover, should the street be on an incline, the water runs downhill from the actual point of leakage. This is a great annoyance. The leakages into the sewers are usually discovered by sewer-men. Some few years ago a case in point occurred in Oxford Street, on the incline near Bond Street. A cone about 3 feet in height suddenly appeared in the wood pavement at the bottom of the incline; and from it a small quantity of water issued. This was found to proceed from a $\frac{1}{2}$ -inch pipe supplying a drinking fountain at the top of the incline. The water had accumulated under the concrete till it drove up the surface. On another occasion a 30-inch main burst at Notting Hill; and the water not finding a ready outlet at the surface, on account of the concrete substratum, forced its way laterally into cellars, basements, and kitchens, and finally forced up the pavement. It cost £500 to reinstate everything and to pay proper compensation. A serious objection to wood pavement is that so much of it requires to be opened up and relaid beyond the actual size of the opening necessary to effect the repair of the pipe. This is a source of great expense. The officials of the Company are of opinion that there is more danger where the road is covered with concrete, carrying either asphalt or wooden setts, than in ordinary cases. In the interests of water companies wood pavement should be laid on gravel and sand well consolidated, and not on concrete. Wherever asphalt is employed, there should be subways for the pipes.

There are in the district of the Southwark and Vauxhall Water Company many miles of streets paved with asphalt, wood, or granite setts laid on a concrete foundation; also wood blocks laid on cross timbers. In all these cases the greatest difficulty is experienced in tracing leakages, owing to the distance often travelled by the leak before it shows on the surface, or in the basements of the houses. This difficulty is frequently increased by the water getting into disused surface drains, numbers of which exist in the older portions of the district. The pipes are laid without special reference to the distance from the houses. The usual practice is to place them in the roadway at about 3 feet from the curb; but this cannot always be done in the main roads, owing to the number of other pipes—for gas, water and telegraph purposes. The pipes used by this Company are of iron, cast vertically, and jointed with lead. The nature of the ground varies considerably in different portions of the district. In nearly all cases any considerable leakage forms a great cavity under the concrete, which rarely gives any intimation of its existence. In some cases leakages from pipes 4 inches diameter have occasioned cavities which required 18 cubic yards of material to fill them up. An important aid to the detection of underground leakages in pipes up to (say) 7 inches diameter, is afforded by Deacon's waste-water meter. These are used by the Company in all districts that are under constant supply; and whenever a leak occurs, the meter indicates its existence, and the approximate amount on the diagram. The leakage is then localized in the manner usually adopted with this system.

THE GAS AND WATER COMPANIES' DIRECTORY, ETC.—We have received a copy of the twelfth issue of the "Gas and Water Companies' Directory," edited by Mr. C. W. Hastings, and published by Messrs. Hazell, Watson, and Viney, Limited. The directory is accompanied by the "Gas and Water Works Statistics," compiled by the same gentleman; and the whole forms a very useful work of reference for all who are engaged in the supply of gas or water. The particulars given are supplied mainly by the officials of the companies or local authorities to whose undertakings they relate; and therefore they may presumably be regarded as reliable. We are assured in the preface that in no previous year has the number of returns been so large; and thus the present edition of the book must be considered as an improvement upon its predecessors. The Editor has noted most of the recent changes in the management of gas-works; though, unfortunately, the work had to go to press with a few unrecorded. The book is bound, as before.

Register of Patents

DISTILLATION OF AMMONIACAL LIQUORS.—Wyllie, R., of Warrington. No. 11,799; Aug. 3, 1887. [8d.]

This invention relates to the distillation of ammoniacal liquors—more particularly such as chloride of ammonia—for the extraction of ammonia therefrom; and it has particular reference to the ammoniacal liquors produced or used in the ammonia-soda process.

Fig. 1 is a sectional elevation of a distiller embodying these improvements; and fig. 2 is an outside view of the apparatus. Figs. 3 and 4 show cross sections of the apparatus.

A is the casing of the apparatus having a number of manholes therein; B and C are alternate trays, over which the liquor is passed a number of times in the upper portion of the apparatus; and D trays over and round which the liquor is passed in the lower portion. E is the chloride of ammonia inlet; F, the steam inlet; G, the milk-of-lime supply pipe; H, the chloride of calcium outlet; and J, the steam and ammonia outlet—all of which are provided in the ordinary way with controlling valves. L is a central hollow column, to which the inner edge of the trays D are secured, and around which the liquor circulates in the trays; and I are syphon pipes through which the steam passes from one tray to another. A number of these pipes are used in each tray; and their exit orifices are all arranged at an angle to the diameter of the plane of the circle in which they lie. K are conduits through which the liquor flows from one tray to another. The trays B are circular, and placed concentrically within the casing A, leaving thereby an annular space between their peripheries and the case. The trays C are provided with a central aperture of less diameter than B. Both trays are shallow, and are provided at the part from which the liquor overflows, with serrated edges.

The circulation and agitation carried on in each of the trays D, together with the heat of the steam will, in the presence of the milk-of-lime, free the ammonia from the liquor, which passes with the steam to the outlet J. The steam, however, before leaving the outlet has (after leaving the uppermost tray D) to pass through the ammonia chloride as it falls from the trays B and C, and C and B; and in so doing heats it thoroughly and also drives off any free ammonia in the liquor. It is preferred that the apparatus shall be so operated that when the liquor arrives at the point where the milk-of-lime is added, it shall be thoroughly heated—say to about 200° Fahr.—and that by the time the steam and ammonia leave the apparatus they are comparatively cool.

SYPHONS FOR GAS SCRUBBERS.—Cutler, S., of Millwall, E. No. 11,867; Sept. 1, 1887. [6d.]

This invention relates to the construction of an automatic syphon in such a manner as to discharge any desired quantity of liquid less than the maximum capacity of the vessel in which it is inserted. It is especially designed for supplying liquid to gas scrubbers; but it is equally applicable for use in connection with the flushing of sewers, or for any purpose where variable quantities of discharge are required.

The illustration shows a vertical section of the tank or chamber A, through the bottom of which the long leg B of the syphon is inserted; the bottom of the syphon being sealed or not with liquid in a vessel below.

Over and encircling the long leg is placed a bell or short leg C of the syphon, supported in any other suitable manner. In this short leg of the syphon, holes are made at appropriate distances; each hole being provided with a plug D, or cock for opening and closing the passage. When it is desired to discharge the maximum quantity, all the holes are closed by plugs D or cocks; and the syphon acts in the usual manner. But if a less quantity be required, then, by removing the plug or opening the cock of any hole or passage, the discharge ceases. The liquid in the tank then reaches the level of that particular hole, in consequence of the admission of air or gas to the bell or short leg of the syphon.

It should be noted (says the patentee) that, although the tank may be only partially emptied at each action of the syphon, the liquid is always drawn from the bottom, and therefore no stagnation occurs.

GAS-ENGINES.—Atkinson, J., of Hampstead. No. 11,911; Sept. 2, 1887. [8d.]

This invention relates to a modification in the construction of the now well-known "Atkinson" engine.

In the specification of patent No. 3522 of 1886, there was described a gas-engine in which the single-acting piston was caused to make four strokes for each revolution of the crank-shaft—one for drawing in the explosive mixture, one for compressing it, one for performing work due to its ignition and expansion, and one for the exhaust. Means were also described to allow of the expansion stroke being made longer than the drawing-in stroke, so as to obtain the benefit of carrying this expansion to any desired extent. The present invention is designed merely for the purpose of making the amount of expansion variable whilst the engine is running.

REGULATING THE QUALITY OF CARBURETTED VAPOUR OR GAS.—Frost, E. J., of Philadelphia, U.S.A. No. 6496; May 1, 1888. [6d.]

The object of this invention is to overcome the difficulty attending the use of carburetters, due to the fact that the saturation of the air-current varies greatly, so that the flame is at times smoky from excess of hydrocarbon.

In the illustration, A and B are two cylindrical closed vessels, communicating with each other at the top by a horizontal passage R. An annular perforated pipe C extends around the lower portion of the vessel A, and is provided with an external coupling, to which the exit pipe of the carburettor (not shown) is attached. Within the annular pipe C is a smaller perforated pipe communicating with an exterior air-blast pipe D. This pipe (in communication with the main air-blast supply of the carburettor) is provided with a normally closed puppet valve O, whose stem N rests upon the surface of a flexible diaphragm or aneroid M, mounted upon the top of the passage R, but isolated from the interior of it. A pipe L leads from the pipe D (at a point not under the control of the valve O) to a valve chamber T, mounted upon the top of the vessel B. From this valve chamber a pipe P leads to the interior of the space beneath the diaphragm. Upon suitable supports G, within the space R, is mounted a balance beam F F', carrying upon the arm F a float E (preferably an air-tight globe of thin copper), and upon the other arm a counterweight H, and a vertical valve stem I, which extends through the top of the vessel B, and into the chamber T. The stem is provided with two puppet valves facing in opposite directions within the chamber, and so arranged that when one is open, communication is established between the pipes L and P, and consequently the full pressure of the air-blast in the pipe D is transmitted to the underside of the diaphragm M. When, however, this valve is closed, the other valve is open, and the pipe then communicates with the enlarged upper portion K of the chamber T, which is open to the outside air. The stem I terminates in a cup J, in which shot may be placed to obtain a counter-balance of the utmost nicety. At the bottom of the vessel B is a coupling pipe S, which leads to the burners.

The operation of the device is as follows:—The normal quality of vapour having been determined, the counter-weight upon the arm F' is so adjusted that when the vapour is passing through the vessels A and B, the weight of the globe E just suffices to hold the valve up against its seat. If, however, the current becomes too highly saturated, the increase of density floats the globe E upwards, and by depressing the arm F' opens the valve. This admits the air current from the pipe D beneath the diaphragm M, and distends it; raising the stem N, and opening the valve O. The air current then passes down through the continuation of the pipe D, and enters the annular pipe issuing through the perforations and mingling with the arriving vapour current in the annular pipe C so as to dilute it. The consequent reduction of density causes the globe E to sink, and when the normal point has been reached, its descent closes one valve, opening at the same time the other one, permitting the escape of the air under pressure from beneath the diaphragm M. This diaphragm then falls and permits the valve O to close, cutting off the diluting air-current.

GAS MOTOR ENGINES.—Southall, J., of Worcester. No. 7934; May 30, 1888. [11d.]

This invention relates to gas-engines of the kind described in patents No. 12,424 of 1885 and No. 15,472 of 1886.

The proposal is to employ two equal cylinders, each closed at both ends, placed horizontally side by side, and having their piston rods passing through stuffing-boxes and linked to the same crank on a crank-

shaft. The cylinders have ports and passages governed by valves for the admission of gaseous mixture and the discharge of products of combustion, to and from each of their four spaces—i.e., the spaces on both sides of the two pistons. The valves are so operated that the four strokes constituting a complete cycle (one for drawing in the charge, one for compressing the charge, one for propelling by the firing of the charge, and one for expelling products of combustion) are performed successively in each of the four spaces; the four operations being so timed that at each stroke, a different operation goes on in each of the four spaces simultaneously—the action of the engine being thus to a large extent equalized. The two front spaces communicate with a reservoir by passages governed by valves worked by the engine, and the two hinder spaces communicate in like manner with another reservoir. The valves are so timed that during the first part of a stroke, while one piston is compressing the charge of gaseous mixture behind it, and the other is expelling the products of combustion, a portion of the charge undergoing compression is forced into one of the reservoirs, and is there retained till the pistons have reached the ends of their strokes. A valve is then opened, allowing compressed fluid from the reservoir to rush into the space whence the products of combustion have just been expelled, driving out the residue of them, and taking their place as part of the next charge. By these arrangements, each of the four spaces is in its turn cleared of the products of combustion, and is charged with combustible mixture which is not vitiated to an appreciable extent by admixture of any residue from previous combustion.

THE PUBLIC LIGHTING OF MALVERN LINK.—This matter has recently been referred to in our pages. It may be remembered that the Malvern Link Local Board, after failing to come to an arrangement with the Gas Company to light the district with gas, advertised for tenders for lighting it with oil, and when in possession of them it was found there had been a misunderstanding with the Gas Company—the Board not knowing that the Company intended to include in their tender the cleaning, lighting, and extinguishing of the lamps. It has now been decided to accept their terms to do this and supply gas at 4s. 6d. per 1000 cubic feet.

THE PRICE OF GAS AT BIRKENHEAD.—At the meeting of the Birkenhead Town Council last Wednesday, a recommendation of the Gas Committee that the rebate for the reduction of price account be increased from 1d. to 3d. per 1000 cubic feet of gas to consumers by meter from and after the 25th of September next, came up for consideration. Alderman Walker moved that the recommendation be referred back. He said his experience of reductions was that the more the price of gas was lowered, the more the consumers had to pay when they received their gas bills. He had to pay more now for the gas at 2s. 9d. per 1000 cubic feet than he had when it was 4s. 9d.; but he supposed this was caused by greater pressure being put on at the works. He wished they could either give the consumers better gas or meters that were honest. He did not believe people burned the quantity of gas for which they were charged. Mr. Little said five or six years ago the same complaint was made by Alderman Walker at the time a reduction was made in the price of gas. Their Engineer (Mr. T. O. Paterson, Assoc. M. Inst. C.E.) then took the accounts of every member of the Council and compared them with the accounts of the corresponding quarter of the previous year before the reduction took place. He found that there was a reduction of more than 9 per cent. in the price paid for gas consumed. No doubt Alderman Walker's bill had been amongst the others; and what he said now was simply untrue. The amendment not being seconded, the recommendation was agreed to.

THE FENTON LOCAL BOARD GAS UNDERTAKING.—At the meeting of the Fenton Local Board last Tuesday, the annual report of the Gas Manager (Mr. F. H. Darwin), an abstract of which appeared in the JOURNAL for June 5 last, was referred to. Mr. J. Gimson remarked that the Gas Committee considered it very satisfactory. The works were in an improving condition, and there was every reason to believe they would continue to improve; and that this year would be a much more satisfactory one than some of the preceding years. Mr. Hawker alluded to some correspondence which had appeared in the newspapers relative to the report. Mr. Gimson said a satisfactory answer could be given to the letters; but for certain reasons it had not at present been made. Mr. Hawker thought that the way in which the report was worded was calculated somewhat to mislead the ratepayers, though he did not think the Gas Committee had any such intention. Mr. Gimson said a mistake had occurred in attributing £2500 as net profit, and omitting to state that out of this sum principal and interest on loans had to be paid. This expenditure reduced the net profit to something like £146. The £500 which was paid over to the rates was really a portion of the profits of the first two years' working. Then the gas was reduced in price to 3s. per 1000 cubic feet; and consequently, instead of there being a profit, there was a loss of about £186. As he had already stated, the Committee (although the price of gas had been reduced) hoped this year to show a much larger profit, though they did not expect any very great things. The gas-works had to pay the interest on the money spent in the construction of a road, which was about £133. If this sum had been reckoned last year, it would have made the profits for the year about £280.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

PUBLIC LIGHTING BY OIL AT ERITH.

SIR,—Secretaries are writing to me for information of the doings of the wonderful Defries Oil Company at Erith; and, with your usual courtesy, I feel assured that you will insert a few remarks on a personal visit I made to see these public oil-lamps last Saturday evening, and thus save me from a long correspondence on this subject with individual secretaries and managers.

Let me say, in sort, that the exhibition I witnessed on the above-named evening was a partial failure. Many of the lamps were smoking; there was no uniformity in the light that was afforded; and I looked in vain for a lamp above 10-candle gas power. The most influential newspaper in the district was perfectly silent upon the subject of this "great light," although the several members of the Local Board had during the week, driven about the district in a cab to try and find their 30-candle power lamps. There was something very ominous, to my mind, in this omission on the part of the local "Thunderer;" and long before I arrived at Erith I was fully convinced there was "something rotten in the state of Denmark."

I arrived about six o'clock, walking from Crayford; and between that village and the Public Hall, Erith—a distance of over two miles—not one lamp was alight, neither could I see any public lamps alight anywhere. This was long after sunset; and it is mentioned as an illustration of the difficulty of getting some 250 lamps lighted up quickly upon this system. (It takes 2½ minutes, on the average, to light each lamp.) On the previous Saturday, I waited at the Local Board's office until 10 p.m. to see their lamp lighted; but the lamplighter had not arrived when my train started. On the last occasion, however, as all Erith was abroad to see this "great light," my determination was to wait in Erith until the poor lamplighter could get round to light up the main street before all the shops were closed. My friend and I waited an hour; and at nine o'clock the lamplighter, with his ladder and matches and stock of extra chimney-glasses, was just arriving at the Public Hall. We followed up, before him and behind him, and saw him light up a number of lamps; and then inspected those that he had previously lighted. I was particularly struck with the great want of uniformity in the light; and was informed that after the lamps are lighted, the lamplighter has to go over his ground again and adjust all the lamps (turn them up or down as the case may be), and renew the chimneys that are "apt to fly" too often.

The lamp has a tank at the top, with tubes on either side—one for oil and the other for air; and white opal under the tank throws the light down upon the pavement. A man with a ladder and a can fills the tank through a funnel during the early part of the day; and this operation of filling and cleaning the chimney and the lantern takes about a quarter of an hour for each lamp. The contractor has painted many of the columns a pretty Post Office red or scarlet, which shows up in good contrast with the green of the hedges in the rural parts of the district, and was the only improvement I could give the Local Board credit for in this matter. The new lamps necessitated new lanterns and new spiders and ladder-stays, which are charged some 38s. 9d. each extra.

Oil-lamps are a good substitute for gas where the latter cannot be obtained or paid for; but general regret and disappointment were expressed by the ratepayers at the contrast between the 5-feet gas-flames and these puny 10-candle power oil-lamps. The announcement was made with a big flourish of trumpets that the ratepayers were to have 30-candle power oil-lamps instead of the 14-candle gas-lamps, and they cannot see it, and feel that they have been hoaxed up to this date. Should any of my brother secretaries pay a visit to Erith, to inspect for themselves, let me warn them not to make the lamp-columns a resting-post for their weary shoulders, as, in filling the lamp-tanks from the top, a quantity of oil appears to be spilt at every lamp, and the asphalt pavement was pretty freely saturated with oil.

But I would add that we must not overlook the broad fact that oil has become a powerful rival, and that a partial failure will not daunt the Oil Company from endeavouring to get 5 per cent. profit if they cannot get 40 per cent.; though doubtless they will try in every possible way to give satisfaction to the Local Board, and keep us out of the field as long as they can. The "moving spirits" in the Company belong to the most persevering and indomitable race on the face of the earth; and are no mean adversaries in business transactions, and must not be despised. They have got a three-years' contract; and if they do not succeed at first they will "try, try again." The Local Board having expected 30-candle power lamps, will endeavour to get their "pound of flesh;" and the Oil Company will try and get a dividend out of their contract; and it does not require a very far-sighted man to see that we have not yet heard the last of the action of the Erith Local Board and their oil public lamps.

R. P. KEYS,

237, Sotuhwark Bridge Road, Secretary, West Kent Gas Company.
 Aug. 1, 1888.

As confirming one statement made in the above letter—that the lighting of Erith is "a partial failure"—it may be mentioned that one of the local papers last week published the following paragraph:—"On Wednesday evening (the night of the severe storm), we have been informed that a number of the lamps were out. This has been accounted for by the fact that the rain got into the oil reservoir during the process of filling. In the Queen's Road, Avenue Road, Crayford Road, High Street, and other leading thoroughfares, several were out during the storm; and complaints have reached us of numerous lamps being also out at Belvedere the same evening."—ED. J. G. L.

THE PUBLIC LIGHTING OF YORK TOWN.—At a special meeting of the Lighting Inspectors of York Town (Surrey), held on Friday, the 27th ult., a letter from the Gas Company was read, in which the Directors reminded the Inspectors of their claim upon them for £5 11s. 11d. in respect of the last contract, and stated that when this was settled, and not before, they would reply to the Inspectors' question as to future supply. After the reading of this letter, the Inspectors decided to light the town with oil. A letter was ordered to be sent to the Gas Company, asking them to disconnect all the lamps from the mains.

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, JULY 30.

The Llanelly Local Board Bill was read the third time, with the amendments, passed, and sent to the Commons.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 1.

The Municipal Corporations (Local Bills), Ireland, Bill was read a second time, and committed.

THURSDAY, AUG. 2.

A petition was presented by John Williams for an inquiry in connection with the Pontypool Gas and Water Company.

SATURDAY, AUG. 4.

The Municipal Corporations (Local Bills), Ireland, Bill, as amended, was considered, read the third time, and passed.

Miscellaneous News.

THE GASLIGHT AND COKE COMPANY.

The following reports, with the accounts showing the working of this Company during the six months ending June 30 last, will be submitted to the proprietors at the half-yearly general meeting to be held on Friday next:—

Report of the Directors.

The Directors herewith submit the accounts for the half year which ended on the 30th of June last.

The business of the Company has continued to make sound progress; and an improvement has taken place in the value of residual products.

The receipts on revenue account have amounted to £1,576,301 0s. 10d.; and the expenditure has been £1,010,389 0s. 11d.

After the requisite deductions for fixed charges, there remains, with the addition of the unappropriated profit brought forward from the last account, a divisible balance of £633,021 16s. 10d.

The Directors recommend a dividend on the ordinary stock at the rate of 13 per cent. per annum, which will absorb £355,459 and leave the sum of £277,562 16s. 10d. to be carried to the credit of the current half year.

A Bill for the continuance of the Coal and Wine Dues was introduced into the House of Commons at the commencement of the present session; but has since been withdrawn. The existing power to levy these dues will expire in the middle of next year.

The Bill of the Metropolitan Board of Works, to which allusion was made in the last report, has been dropped, and the legal position of the Company in relation to damage caused by steam-rollers, which the Bill sought to alter, remains unaffected.

The adverse decision of Mr. Justice Kekewich in the case of the Company *versus* the South Metropolitan Gas Company was confirmed by the Court of Appeal, whose judgment, however, was delivered in such terms as suggested to the Directors the expediency of further prosecuting their appeal; and they were advised by Counsel that, with such a judgment, they were bound, in the interests of the Company, to obtain the decision of the highest tribunal. An appeal to the House of Lords has therefore been lodged, and is now awaiting a hearing.

WILLIAM THOMAS MAKINS, Governor.

Horseferry Road, Westminster, S.W., July 17, 1888.

Construction and Carbonizing Department.

I beg to certify that the whole of the Company's gas manufacturing and storage stations have been kept in good order and efficiency during the past six months. I have further to report that, in order to meet the anticipated maximum day's increase during the next winter, the last of the twelve retort-houses at Beckton is being fitted up, together with all the apparatus in connection therewith. This will add 5½ million cubic feet to the total daily manufacturing power of the Company. A large gasholder tank is also being constructed at the Bethnal Green station of the Company, to accommodate a gasholder to contain 4 million cubic feet.

G. C. TREWEY,

Constructing and Carbonizing Engineer-in-Chief.

Distribution Department.

I hereby certify that the whole of the distributing plant under my charge has been maintained in a thorough state of repair and efficiency during the past half year.

ROBERT HARRIS, Distributing Engineer.

Products Department.

I hereby certify that the whole of the plant, engines, boilers, stills, trucks, machinery, and tools, in connection with the Company's products works under my charge, have, during the past half year, been maintained in good working order and repair.

THOS. WILTON, Superintendent of Products Works.

Appended to the report is the statement of accounts therein referred to. These will be given next week.

PUBLIC LIGHTING AT CONSETT.—The new agreement just entered into between the Consett Local Board and the Shotley Bridge Gas Company is to the effect that the latter are to light the lamps for 1600 hours between August and April at the cost of £2 2s. each lamp.

STROUD WATER COMPANY.—The half-yearly general meeting of this Company was held at the London Offices last Tuesday—Rear-Admiral Bythesea, V.C., C.B., in the chair. The Secretary (Mr. P. H. Stephens) having read the notice convening the meeting, the Chairman moved the adoption of the Engineer's report and the balance sheet to June 30 last, copies of which had been sent to the shareholders. He said the works had not progressed as well as they should have done; but the contractors had had a good many difficulties to contend against, owing to the unfavourable reception of the project in Stroud. The applications for the supply of water were coming in very fairly; but they could hardly expect the demand to reach its full force until the works were completed. What seemed most necessary was to endeavour to create an interest in the works in Stroud itself; and to add to the Board one or two local Directors, so that a quorum could always be obtained by one Director going down from London. The report was adopted. The great need of the district being a good supply of soft water, the Chief Engineer of the Company was instructed to inquire into the various softening processes now in use. Steps are being taken to place a local Director upon the Board.

SOUTH METROPOLITAN GAS COMPANY.

DIRECTORS' HALF-YEARLY REPORT.

The following is the report of the Directors of this Company, which, with the accounts for the six months ending June 30 last (to appear next week), will be presented to the proprietors at the half-yearly general meeting on the 15th inst.:—

"The past half year has been uneventful but satisfactory, as is shown by the accompanying accounts. There has been an increase the corresponding period of last year of 4.7 per cent. in the gas sold; but, owing to the price being lower than in the March quarter of 1887, the addition to the gas-rental is proportionately smaller—amounting to \$8111. Products have been in somewhat better demand, and have yielded £22,061 more than last year. As the supply of tar still evidently exceeds the demand, 39 per cent. of the total make has been used as fuel. Exhibitions of various kinds of apparatus for the use of gas, coupled with cookery lectures, have been held in all parts of the Company's extensive district, and have resulted in a great demand for gas-stoves, and in the dissemination of much practical information amongst consumers of the best and most economical methods of using gas for lighting and for many other purposes. Some large regenerative burners shown at these exhibitions gave a magnificent light; proving that gas can hold the field against all competitors. Your Directors have taken an active part in opposing the renewal of the Coal Dues, on the ground that they are an unjust tax on the consumers of gas and coke, who thereby pay more than their share of rates for local purposes. The Bill promoted by the City Corporation and the Metropolitan Board of Works failed to secure Government support, and has again been withdrawn. Should it be revived next session, it will meet the same uncompromising opposition. This oppressive tax, unless renewed, will expire next July; in which case your Directors intend to give the entire benefit of the saving thereby effected to the consumers. The profit on the revenue account amounts to £144,763 12s. 10d. This with £5263 17s. 3d. brought forward from last half year, and the interest on the reserve fund £4606 0s. 1d. (less £933 7s. 8d., the difference of interest paid and received on loans and deposits), gives a sum of £153,700 2s. 6d. Interest on debenture stock and bonds amounts to £13,667 5s. 1d., which leaves £140,032 17s. 5d. A dividend of 13 per cent., less a fraction undivided as usual, will require £123,947 10s. Your Directors therefore recommend the said dividend; leaving a balance of £11,085 7s. 5d. to be carried forward to the current half year."

BRENTFORD GAS COMPANY.

THE DIRECTORS' HALF-YEARLY REPORT AND ACCOUNTS.

The report of the Directors of this Company for the half year ending June 30 last, with the accounts for this period, has been issued, and will be presented at the general meeting of shareholders next Friday. The accounts show a sum of £64,414 10s. 6d. available for division. The Directors recommend the declaration of the following dividends, subject to income-tax:—At the rate of 5 per cent. per annum on the 5 per cent. preference stock, 11½ per cent. per annum on the consolidated stock, and 8½ per cent. per annum on the new stock (1881). The Directors report with pleasure that the sale by tender of £15,000 of new stock (1881) in March last realized £24,497; the whole amount having been tendered for above the minimum price named in the conditions. The sulphate of ammonia plant at Southall, mentioned in the last half-year's report, is now in satisfactory operation; and the works and machinery (under the supervision of the Company's Engineer, Mr. F. Morris, M. Inst. C.E.) are in efficient order. The amount received from the sale of gas to private consumers in the first six months of the present year was £67,188 12s. 5d.; for public lighting, £7499 0s. 5d.—together, £74,687 12s. 10d. Stove and meter rentals produced £2843 13s. 3d. Residuals yielded £16,292 3s. 11d. The total receipts were £93,876 16s., against £85,378 in the corresponding six months of last year. The increased receipts for gas come to about £3000; coke returned about £1500 more, tar about £750 more, and ammoniacal liquor about £600 more. The manufacturing expenses were £46,953 9s. (coals costing £32,290 12s. 8d.); those relating to distribution came to £5424 17s. 6d.; rents, rates, and taxes to £4215 13s. 11d.; the lighting and repair of the public lamps to £1244 17s. 11d.; management expenses to £3564 11s. 2d.; miscellaneous items making up a total of £62,102 8s. 11d., against £61,322 in the corresponding six months of 1887. The balance carried to the profit and loss account is £31,774, against £27,056. The quantity of coal and cannel carbonized was 46,883 tons, against 45,111 tons. The following are the working results:—Gas, 502,631,000 cubic feet; coke, 31,338 tons; breeze, 3925 tons; tar, 469,392 gallons; ammoniacal liquor, 12,691 bbls of 108 gallons. The Company's paid-up capital on June 30 last amounted to £700,211 17s. 4d., of which £686,006 6s. 8d. had been expended.

SCARBOROUGH GAS COMPANY.

The Half-Yearly General Meeting of this Company is to be held next Saturday, when the Directors will present their report, with the accounts of the undertaking for the six months ending June 30 last. The revenue account shows a net profit of £6021. The balance of net revenue, including £465 4s. 1d. remaining from last half-year's account, after the transfer of £779 8s. 2d. to the reserve fund, and after deducting all interest charges for the half year, is £5871 9s. 7d. Out of this sum, after providing for the dividend on the 5 per cent. preference stock, the Directors recommend the payment of the maximum dividends upon all other stocks of the Company. The payment of these dividends will absorb £5036 11s. 5d.; leaving a balance of £834 18s. 2d. to be carried forward to next half-year's account. The operations of the last twelve months having resulted in a considerable increase of revenue, the Directors have announced a reduction in the price of gas of 3d. per 1000 cubic feet to all classes of consumers as from the 1st ult.; making the present net price 2s. 9d. per 1000 cubic feet—a rate which the Directors trust will encourage still further the use of gas for the many purposes for which it is available. Taking the accounts now before us with those for the preceding half year, we find that the cost of coal, including labour, for the twelve months was £10,219; being at the rate of 13s. 7.72d. per ton, and 1s. 3.34d. per 1000 cubic feet of gas sold. Deducting the amount yielded by the residuals (£4927), the net cost was £5292; being at the rate of 7s. 0.78d. per ton, and 3.799d. per 1000 feet of gas sold. The other items of expenditure make up a total (less residuals) of £13,100; being 17s. 5.87d. per ton of coal, and 1s. 7.79d. per 1000 cubic feet. The revenue from gas (including public lamps) was £24,371, the meter and stove rents were £991, and miscellaneous receipts bring up the total to £26,046; being at the rate of £1 14s. 9.26d. per ton of coal, and 3s. 3.34d. per 1000 cubic feet of gas sold. Deducting the expenditure, as above, there is shown a profit of £12,945, of which £11,359 is required for the payment of dividend and interest; leaving a surplus of £1586—equal to 2s. 1.41d. per ton of coal carbonized, and 2.39d. per 1000 cubic feet of gas sold. The quantity of coal and cannel dealt with in the works (which are under the supervision of Mr. W. J. Moon, the Secretary and Manager) was 14,981 tons, which produced 170,263,900 cubic feet of gas, of which 158,870,117 cubic feet were sold. On this sale the concession announced to the consumers by the Directors in their report will come to close upon £2000.

THE SALFORD CORPORATION AND THE GAS INSTITUTE.

At the Meeting of the Salford Town Council last Wednesday—the Mayor (Alderman A. L. Dickens) presiding—there was a remarkable scene when Mr. Mandley brought forward the resolution of which he had, as mentioned in the JOURNAL last week, given notice, in these terms:—"That, in view of the positive and apparently incontrovertible assertion made by Mr. George Bray, C.E., in his pamphlet, entitled 'Corrupt Practices in the Gas Industry,'—namely, 'that corruption in the gas industry has been largely fostered by the policy pursued by the Council of The Gas Institute'—no further subscription be paid, nor any other support whatever be afforded by or on behalf of this Corporation, to The Gas Institute; and that it be a standing instruction to the Gas Committee that they shall, whenever occasion arise, express their strong disapproval of membership of the said Institute being entered into or maintained by any of their officials."

On the motion being reached, Mr. PHILLIPS submitted, as a point of order, that it could not be entertained, because the Corporation did not pay any subscription to The Gas Institute.

Mr. MANDLEY: The very frivolous objection of Mr. Phillips you will dispose of; and I am surprised that he should display *animus* at the outset.

Mr. PHILLIPS: Are we to have our time taken up by a discussion on The Gas Institute, with which we have nothing to do?

The MAYOR: We have subscribed to the Institute?

Mr. PHILLIPS: Years ago. We are not subscribing now.

Mr. SNAPE: Is this the proper place to "wash the dirty linen" of The Gas Institute?

Mr. JACKSON: Has Mr. Mandley received a retaining fee from Mr. Bray?

Mr. MANDLEY: We all know the purity of Mr. Jackson's motives. I wish him to be quiet, and if he has any brains to show them. (Laughter.) I shall take my time. Alderman Bowes and other aldermen are trying to waste as much time as possible.

Alderman Bowes protested against this statement.

Mr. MANDLEY (after appealing to the Mayor to preserve order) proceeded to say that every member of the Council had been furnished with a copy of a pamphlet he held in his hand—a pamphlet by Mr. George Bray, of Leeds, on "Corrupt Practices in the Gas Industry" [Mr. SNAPE: I have not received one.] He hoped every member had read the pamphlet; and if not they had not done their duty. He would not commit himself to everything that the pamphlet stated; but he might give the Council the gist of it. It stated that the honest trader had no chance against bribing firms and venal gas managers. As an illustration of this, it was asserted that a certain firm of meter makers in the year 1886 paid to gas managers alone commission on not less than three-fourths of the whole of their trade. In this connection he might say that he saw, in the JOURNAL OF GAS LIGHTING, that some of the meter makers were advertising that they would not any longer pay those illegal commissions. The pamphlet further said that considerations of quality or price were ignored by the venal managers, who thought only of those secret commissions; and that this vile system did not merely prevail in coal contracts, but in relation to everything bought or sold in the manufacture of gas, and, unless commission was paid, no trade could be done. The pamphlet further set forth that certain consulting engineers and many gas managers were either directors or shareholders in companies whose articles they strongly recommended to their employers. A corporation called in a consulting engineer and—

The MAYOR (interposing) said he had been from home, and did not see this resolution until Tuesday. Had he seen it earlier, he should never have allowed it to go on the agenda paper. The Council did not subscribe to The Gas Institute; and why did they "wash the dirty linen" of an institution with which they had no cognizance? It would be quite time to engage in a discussion on this question when there was any intention on their part to subscribe.

Mr. MANDLEY said he had made notes, and would confine himself to them.

The MAYOR: Why should we rake up these matters here, when we have nothing to do with The Gas Institute?

Mr. MANDLEY: Having the highest regard for yourself, Mr. Mayor, I am sorry that you should have interposed with these remarks. I do not take this course without first obtaining competent advice. Our Standing Orders and Municipal Law are framed on the hypothesis that nothing whatever shall be excluded from the agenda paper merely as a matter of taste. I am positive that if I were to apply for a *mandamus* you would be compelled to place the motion on the paper; but I do not wish to take this course. I have consulted a Town Clerk whose opinion is held in high esteem; and I say that this motion could not—

The MAYOR: Are we to understand that any member can put a notice on the agenda paper to enable him to vilify an institution to which we do not subscribe?

Mr. MANDLEY: We have subscribed. ("No.") Somebody said "No," which is the result of ignorance; for we have not only paid subscriptions to the institution, but also the expenses of the former Gas Engineer to go away—

Mr. PHILLIPS: What is the use of discussing these matters, which do not concern the Corporation?

Mr. MANDLEY: The expenses of the late Gas Manager were paid by— Alderman WALMSLEY: Have you not ruled, Mr. Mayor, that the point raised by Mr. Phillips is fatal to the motion?

The MAYOR: It places me in a very difficult position, seeing that the motion has been allowed to appear on the agenda paper; but as the point has been raised by Mr. Phillips, I must say that I consider the motion out of order. The Council subscribed in 1882, £5; in 1883, £5; and in 1884, £15, when an exhibition was held at the Crystal Palace, London, to illustrate the comparative merits of gas and electricity. We have not subscribed since 1885. The expenses of the late Gas Manager were paid by himself.

Mr. RYCROFT contended that the latter portion of the motion was regular. It could not be out of order to give an instruction to the Committee.

Mr. SNAPE wished to know if it would be in order to move a resolution instructing the Committee not to go to St. Petersburg. If Mr. Rycroft was right, this might be done.

The MAYOR: I think it would be quite time for Mr. Mandley's motion when it was proposed to subscribe to The Gas Institute.

Mr. MANDLEY: This matter must go further. Year by year since I entered the Council I have been most abominably ill-treated; and if you rule the motion out of order, I cannot allow it to rest. I ask the Town Clerk, whose credit is at stake, for his opinion; and if I am not allowed to move my resolution, I say it is against all logic and all justice.

Alderman WALMSLEY: We cannot discuss the rule of the chair. If Mr. Mandley feels aggrieved, he has his remedy.

Mr. MANDLEY: Must gentlemen go to law to get what is right? Is this the position members of the Council are to be put in? It would be with very great reluctance indeed that I should appeal from the injustice of the Mayor to the justice of the law.

Mr. GROVES: Would not the final clause justify Mr. Mandley proceeding?

The MAYOR: I do not see any objection to it.

Mr. PHILLIPS: I offer no objection to that.

Mr. MANDLEY: But I object to being "badgered."

Mr. JACKSON thought their time ought not to be wasted in this way.

Mr. MANDLEY: The whole gist of the thing is that we should not subscribe to The Gas Institute; it is an instruction to the Committee that what has been done in the past must not be done in the future. I left off by stating that even the consulting engineers that were called in, and who were paid a considerable sum for their advice, were getting direct profit on the very articles they were recommending should be bought; that The Gas Institute—

The MAYOR: I must decide that you cannot go into these matters.

Mr. COTTRELL: Limit yourself to the latter part of the resolution.

Mr. MANDLEY: I demur to that. If I am not allowed to show why we should not subscribe to the Institute, I am most unfairly handicapped. What has Mr. Bray done that the Council of the Institute should seek to expel him?

Mr. COTTRELL: We all know that.

Mr. MANDLEY: All may not. Some members make a boast that they have not read the pamphlet.

Alderman MAKINSON: If Mr. Mandley gets from the Chairman of the Gas Committee an assurance that the Committee will not subscribe to the Institute, will he not be satisfied?

Mr. LORD (Chairman of the Gas Committee): I shall be pleased to give that assurance. We do not intend to subscribe.

Mr. MANDLEY: I have no doubt I shall be told these statements are purely *ex parte*; that Mr. Bray must produce his legal proofs, or they will not be listened to. If Mr. Bray's charges against the Institute were false, how was it—

Mr. SNAPE: I understood, Sir, you had ruled that The Gas Institute and Mr. Bray are not before the meeting.

Mr. MANDLEY [to Mr. Snape]: You take your seat.

The MAYOR: I must request you, Mr. Mandley, to bring your remarks to a close.

Mr. MANDLEY: I will bring them to a close if you will keep these "terrier dogs" off me. (Laughter.) I cannot proceed for them. If these charges that Mr. Bray has made against the Institute are false, why have they not brought Mr. Bray into Court? Mr. Bray's charges have not been controverted; yet a mean and cowardly attempt—

The MAYOR: I must rule these references out of order.

Mr. MANDLEY: An attempt was made to expel Mr. Bray—(Cries of "Order.")

The MAYOR: Considering that you have had an assurance that the Committee do not intend to subscribe to the Institute, why in the world should we be listening to extracts from the pamphlet of Mr. Bray, which I do not think we have anything to do with. I leave it to your own good sense to bring your remarks to a close.

Mr. MANDLEY: Then I will leave Mr. Bray out, and will take you to something else. On the late Gas Committee, I opposed the payments to Mr. Hunter for going away in connection with the meetings of The Gas Institute. When your late Gas Engineer attended these meetings it was then that he made contracts with these bribing firms.

Alderman HALL: If Mr. Mandley will confine himself to the resolution, it would be better; but he surrounds it with a lot of stuff that has no connection with it. We are not dealing with Mr. Bray's pamphlet at all.

Mr. MANDLEY said he had met with similar treatment to this in the Gas Committee for years. The men who were now opposing his motion formerly spoke of Hunter as a man of genius, and a most competent Engineer; but so long ago as 1875 the Rochdale Corporation—

The MAYOR said this was altogether out of order. He should be sorry to take an extreme course; but Mr. Mandley paid not the least attention to his ruling.

Mr. RYCROFT suggested that the difficulty might be overcome by the adoption of the latter half of the resolution—the instruction to the Committee—with the addition of the words "as at present constituted" immediately after the word "Institute."

Mr. MANDLEY: I will accept that.

Alderman ROBINSON said that the present Gas Manager was a member of the Institute; and therefore the Council had better understand clearly the position in which the resolution would place them. He thought it would be far better to refer the matter to the Gas Committee for consideration, and let them report.

Mr. MANDLEY: I will accept that.

A resolution referring the matter to the Gas Committee was then formally adopted; and the Council proceeded to other business.

A MISHAP TO A HOLDER AT ROCHDALE.—Some inconvenience was caused at Rochdale last Wednesday afternoon by the failure of the gas supply during a period of temporary darkness. A question on the subject was put to the Chairman of the Gas Committee at the Council Meeting on Thursday; and it was elicited that the pressure failed because one of the holders stuck. Mr. T. B. Ball, the Engineer, was on the premises, and the mishap was rectified immediately, but complaint was made that the sudden fall of the holder had the effect of forcing the water out of the meters in some cases. As a result of the extraordinary weather which is being experienced, it is stated that the daily consumption of gas at Rochdale on Wednesday was double what is usual at this time of year.

NEWPORT (MON.) WATER SUPPLY.—The Crumlin section of the water-works now being constructed by the Rural Sanitary Authority of the Newport Union has lately been inaugurated by turning the water into the new mains. The source of supply is a powerful spring situated in the Tongwyn Wood, about a quarter of a mile out of Crumlin, the property of Lady Llanover. This spring is of remarkably uniform volume and purity. It was gauged by Mr. T. Dyne Steel, M. Inst. C.E., the Engineer of the Authority, throughout the summer and autumn of last year, and the lowest yield was 28,350 gallons per day. As regards purity, the water was analyzed by Dr. C. Meymott Tidy in May, 1887, and pronounced by him to be a very good water, pure and wholesome. The water is taken from the eye of the spring direct into the mains by an ingenious arrangement, so that it never sees daylight till it is drawn from the consumers' taps. Close to the spring a brick service-tank has been constructed, holding about two days' requirements of the district in case of any accidental derangement at the spring. In order to supply the high district of Cwmdows, the Engineer has continued the Crumlin mains to the neighbourhood; and several residences situated at an elevation of more than 500 feet above the sea level, are now successfully supplied with water from the Crumlin spring. The whole of the works were designed and superintended by Mr. T. Dyne Steel. Mr. Steel is also constructing for the Authority larger works for the supply of Newbridge, Abercarn, and Cwmcarn; but as these involve a storage reservoir, now in course of construction, in the Gawn Valley, it will take about three months to complete the water supply of the whole district.

THE TRANSFER OF THE EDINBURGH AND LEITH GAS WORKS TO THE CORPORATIONS.

THE GAS COMMISSION AT WORK.

The Edinburgh and Leith Gas Commission held their second meeting on Monday last week—Baillie TURNBULL presiding. Mr. Smith Clark was present, and made the statutory declaration.

The Finance Committee met an hour before the assembly of the Commissioners; and the minute of their meeting stated that they had authorized the payment of £27,000 to the Edinburgh Gaslight Company, and of £11,000 to the Edinburgh and Leith Gaslight Company; these being the capital sums on the payment of which, as the Act provided, the gas undertakings should become vested in the two Corporations. The Committee's minutes also contained the following letter from Mr. Adam, the City Chamberlain:—"As authorized by the City Treasurer's Committee, I beg to send you detailed statements of the outlay by the Lord Provost, Magistrates, and Council of Edinburgh in connection with—(1) the opposition to the Edinburgh Gaslight Company's Bill, 1887, and negotiations in that year for the proposed acquisition of the undertakings of the Edinburgh Gaslight Company and the Edinburgh and Leith Gaslight Company by the Town Councils of Edinburgh and Leith; and (2) the promotion of the Edinburgh and Leith Corporations Gas Bill, 1888, which received the Royal Assent on the 24th inst. As instructed by the Treasurer's Committee, I have added interest on the advances by the city at the rate of 4 per cent. per annum. These advances have so reduced the cash balances on the city's proper municipal accounts as to make it desirable that the amounts be repaid by the Gas Commissioners before the close of the city's financial year on the 1st prox." Annexed to the letter were abridgments of the statements of outlay and interest; the totals being as follows:—Opposition to the Edinburgh Gas Company's Bill, 1887, £2952 17s. 1d. Promotion of the Edinburgh and Leith Corporations' Gas Bill, 1888, £3049 1s. 7d.—total advances for outlay, £6001 18s. 8d. Add interest on total outlay, £133 1s. 2d.—together, £6134 19s. 10d. The Finance Committee's minute went on to state that they had authorized the repayment of the above sum to be made to the City Chamberlain without delay. They had also, at the request of Mr. Beveridge, the Parliamentary Solicitor, authorized a further remittance to him of £1500 on account. In order to meet these various amounts, the Committee had asked from their bankers a loan of £50,000 on the short loan system, for a period of either two or three months, as might be arranged. The minute concluded by stating that a remit had been made to a Sub-Committee in regard to the increased accommodation and rearrangement and alteration of the office premises necessary for efficiently carrying on the work of the Commission.

The report was adopted.

The meeting then proceeded to elect an interim Clerk. The names of two gentlemen were submitted—Mr. W. P. Lindsay, W.S., and Mr. J. M. Jack, S.S.C. On a division, Mr. Jack was elected by 11 votes to 7; the appointment being for three months.

Mr. COLSTON moved, and it was agreed, to empower the Works Committee to make arrangements for taking stock of the stores of both Companies at a valuation, as provided by the Act of Parliament.

A vote of thanks was then accorded to the Town Clerk (Mr. Skinner) for his services; it being agreed that he should have something more substantial.

It was also agreed to keep the price of gas the same as at present for another year; and that the quality should be 28 candles.

THE TRANSFER OF THE WORKS.

In accordance with the Act of Parliament, the newly-constituted Gas Commissioners became the owners of the undertakings of the Edinburgh and Edinburgh and Leith Gas Companies at midnight on the 31st ult. The transference was a merely formal matter; the Managers of the two Companies, at their respective works, taking a measurement of the coals and other stores on hand. At the same hour a note was taken of the quantity of gas which had passed through the station meters at the respective works since the beginning of the financial year till that day, and for which each Company is entitled to payment. At noon on the 1st inst., the Clerk to the Commission (Mr. J. M. Jack) paid over £11,000 to the Edinburgh and Leith Company, and £27,000 to the Edinburgh Company, as the amount of goodwill arranged to be paid; to meet which the Commissioners borrowed the sum of £50,000 from the Commercial Bank of Scotland.

On the invitation of the Directors of the Edinburgh Company, a large number of the Commissioners met in the afternoon, at the works in New Street, for the purpose of taking part in the formal handing over of the establishment to the new body. The members assembled in the open space in front of the offices, and there they awaited the presence of the Directors, who had a meeting arranging the details of the transfer. Sir T. Boyd and other Directors shortly after one o'clock emerged from the building, and the ceremony immediately proceeded.

Sir Thomas Boyd said he regretted exceedingly that Mr. Syme, the Deputy-Governor of the Company, was not present, and that in his absence the duty devolved upon him (Sir Thomas) of formally handing over the undertaking and the works to the newly-formed Gas Commission. In doing so, he had very great pleasure, on behalf of the Directors, in wishing the new body every success in the management of the works. The negotiations, as they knew, which led up to the transference, involved very serious and difficult problems. The matters under consideration had to be investigated to the very bottom, and this led to very protracted negotiations; both parties contending—and justly contending—in the interests of their constituents, for what they thought was their due. It was, however, gratifying now to look back upon what had taken place, and say that amid all the difficulties that arose, not a single word was used which they had any reason to regret. It was most gratifying to them all, seeing that matters had come to this stage, that such should have been the case. With regard to the prospects of the newly-formed Commission, there was every reason to congratulate them on the favourable position in which they were placed. The price of coal was very low. The Company had brought the manufacture of gas to a very high state of efficiency; and he believed that the other Company had done the same. Had they continued as a Company, they intended to make some improvements in their works—improvements which would have enabled them to very materially reduce the price of gas; and there was no doubt that had they continued long in office, the price of gas would certainly have been greatly lowered. He had no doubt, further, that when the Commissioners came to consider the matter of reducing the price, they would find themselves in a position to do it. They would, he said, find the working of the concern of a very interesting character; and he thought it was due to the Engineer (Mr. R. Mitchell) to say that he had managed his department in a very efficient way. Indeed, had they continued as a Company, he believed they would have been mainly indebted to him for his advice in effecting such improvements in the works as would have enabled the Directors to reduce the price of gas in the way he had referred to. It was also right to mention

the name of Mr. Cockburn, who had taken charge of the office department, and had always given the highest satisfaction.

Mr. COLSTON, who replied on behalf of the Commissioners, thanked the Directors for affording them an opportunity of meeting them on so interesting an occasion. He had no doubt they would find the works as efficient as Sir Thomas and the Directors stated them to be. It was gratifying to know that the Commission took over this great concern at a time when circumstances were so favorable. He understood that, according to the contract just entered into by the Commission, a saving on the price of coal would be effected to the amount of £15,000. It gave those who had been fighting the battle of the public the utmost satisfaction to know that this was the case. He fully reciprocated every word that had been said by Sir Thomas Boyd with regard to the negotiations.

The whole party, led by Mr. Mitchell, then proceeded through the works, where they examined with evident interest the various stages in the process of gas manufacture. In the afternoon, the Directors and the Commissioners lunched, on the invitation of the former, in the Waterloo Hotel. The chair was occupied by Sir Thomas Boyd, and several complimentary toasts were proposed and duly responded to; "Success to the Gas Commission" being received by the Directors with enthusiasm.

The formal transfer of the works and undertaking of the Edinburgh and Leith Gas Company took place on the afternoon of Thursday last. The Edinburgh members of the Commission assembled at the City Chambers, and drove to the Company's works at Baltic Street, Leith, where the Directors had previously met. On arrival there, the whole company proceeded to the vacant ground immediately behind the offices, where the ceremony of formally handing over the works took place.

Mr. J. TAWSE, Chairman of the Company, said that, on behalf of the Directors, they had very great pleasure in handing over the undertaking; and he was sure that the Commissioners would find in going through the works that they were in good condition, and capable of providing their constituents with an efficient gas supply. The Directors had for years striven to keep up their works to a high degree of efficiency, and to introduce into them all modern improvements. For some years they had been renewing the works—supplanting old material by new. He might take the opportunity of saying that some animadversions had been made in regard to past matters that the Directors had to deal with. It was thought the Company should not have done certain things last year. Now, these were not done last year in consequence of any negotiations that were in progress or anticipated. They were part of the plan which the Directors had been carrying out for a number of successive years—renewing their works by degrees. They only did last year what they had done in former years. All the improvements had been carried out under the charge of Mr. F. T. C. Linton, their Engineer; and the Commissioners would find him a gentleman capable of adequately carrying on the management of their affairs. He further said that, on behalf of himself and the former Directors of the Company, he hoped the transfer of the gas undertakings to the Commission would be productive of much good, and that the Commission would realize their highest expectations. He trusted also that it would be found to be a great boon to the people of Edinburgh and Leith.

Mr. COLSTON, who replied, said that when they first became aware of the necessity for taking over the lighting of Edinburgh and Leith, they saw that it would be absolutely requisite for them to have both gas undertakings in their possession. Of course, it was right for the Directors to make the best bargain they could; and it was also right that, in defence of the public, the Commission should get the best terms. They had had a long and hard fight; and it was gratifying that all parties were pleased, and that now, after all the controversy, they could meet in the most friendly and cordial relation. As to the condition of the works, in the matter of retorts he had the best reason for saying that they were up to modern ideas. The report of Mr. George Livesey, which would shortly be issued, would, he thought, amply testify to this view. He could only trust, in conclusion, that the public interest would benefit by the transfer of the undertaking.

The members of the Commission, accompanied by the Directors and Mr. Linton, then proceeded through the works; all expressing the utmost satisfaction with their condition. They afterwards visited the gasholder stations. The Commissioners and Directors afterwards lunched at the Windsor Hotel, on the invitation of the directorate.

SALTCOATS GAS COMPANY.

The Directors of the Saltcoats Gas Company have lately issued some interesting notes and statistics regarding the concern under their management. The pamphlet embodies a short statement in reference to the early history of gas lighting, which concludes by stating that gas was supplied for the first time in Glasgow in September, 1818; in Paisley and Kilmarnock in 1824; in Irvine in 1829; in Leith in 1831; in Dalry in 1834; in Saltcoats in 1836; in Kilwinning and Largs in 1837; in Girvan and Ardrossan in 1841; in Stevenston in 1856; and in West Kilbride in November, 1856. It will be seen that, with the exception of Glasgow and Paisley, all these towns are in Ayrshire. The construction of the Saltcoats Gas-Works commenced in the summer of 1836; the leading contract being taken by Messrs. Reid and Hanna, Engineers, of Paisley, whose business is now continued by the firm of Hanna, Donald, and Wilson. Gas was supplied to the town for the first time about the end of the year, or early in 1837. The price to consumers by meter was at the commencement 10s. 6d. per 1000 cubic feet; and in 1841 it had been reduced to 8s. A considerable number of the consumers paid for the gas used according to the number and size of jets or lights, and the number of hours they were kept burning. Numerous grievances arose out of this mode of charging, and the surveillance which it necessarily required. Eventually, in the course of the year 1849, after the subject had been much canvassed, it was agreed to let out meters on hire—a system which ultimately became general. It put a stop to "watching," it was more profitable to the Company, and more satisfactory to the consumers on the whole. At the same time it was decided to pay the cost of gas-fittings for weavers' shops, and charge a percentage on the outlay. This proved a considerable boon to the weaving industry, which was of greater importance in Saltcoats in those days than it is now. Up till July, 1883, a charge was made for the hire of meters; but it was then abolished, the Company supplying all meters free. The first gasholder erected at the works served its purpose well for the first 13 years. It continued to be of use for many years longer; but it ultimately became unserviceable, and was sold as old metal in 1882. The second holder was erected in 1849; and in 1874 the third had become necessary. A report to this effect was obtained from Mr. G. R. Hislop, of Paisley, who also recommended other improvements; the whole estimated cost being upwards of £1500. A fourth holder is now in contemplation. The two holders at present in use have a total capacity of 33,044 cubic feet. The average daily make of gas in December, 1887, was 40,863 cubic feet, and in January of this year, 37,650 feet. As to the residual products, only £21 19s. was obtained for them in the year 1888; but in 1883-4 the revenue from this source was almost £200. Last year, however, the sum realized was only £66. The lighting of the town was for a long time a matter involving much annoyance,

owing to the difficulty of obtaining payment for the gas consumed; but in 1859 it was agreed to put 2d. per 1000 cubic feet on the price of gas, so as to ensure that the Company should be paid for the gas. This extra charge was discontinued after the annual meeting in 1864; the Company supplying the gas for the street lamps free. Last year there were about 1120 gas consumers in the town, and the number will be considerably increased this year. The first Manager was Mr. W. Shearer; and for three years his successor was his widow. Several others followed till 1876, when Mr. T. Wilson, now of Coatbridge, was appointed. He was succeeded in December, 1880, by Mr. J. Henderson, the present Manager.

MANCHESTER CORPORATION GAS SUPPLY.		
ABSTRACT OF THE ACCOUNTS OF THE GAS UNDERTAKING FOR THE YEAR ENDING MARCH 31, 1888.		
In the JOURNAL last week (p. 212), we gave the report of the Gas Committee of the Manchester Corporation for the year ending March 31, 1888. We now give a few particulars taken from the accounts for this period, as certified by the Auditors (Messrs. Lees and Graham):—		
PROFIT AND LOSS ACCOUNT.		
EXPENDITURE.		
Coal and cannel	£175,179	17 3
Retort-men's wages	32,550	13 3
Retorts, materials, and setting	11,006	17 9
Labourers' wages and repairs of works, street mains, and repair of hired meters	37,944	6 9
Purifying charges	2,422	13 7
Salaries and wages	14,198	0 10
Collectors' salaries	7,492	12 9
Chief and other rents, rates, and taxes	18,012	3 10
Amount of depreciation written off for the year	33,623	0 9
Stationery, advertising, and stamps	1,428	0 4
Law expenses	95	10 0
Miscellaneous expenses	598	1 8
Official clothing	354	3 11
Painting offices, repair of furniture, and alterations	199	3 11
Subscriptions and donations	72	10 0
Bad debts	853	19 11
Bankers' commission and charges	258	2 8
	£336,289	19 2
Balance, being the gross profit on the year's working	106,072	9 3
	£442,362	8 5
Interest on loans, consolidated stock, deposits, &c.		
Cost of street lighting	£29,832	16 11
Less value of gas (not charged)	20,942	18 10
	8,528	19 4
Transferred to sinking fund	26,454	0 0
Amount paid to the City Fund account during the year	£23,331	0 0
Balance, transferred towards the liquidation of adverse balances on the profit and loss account in past years	17,925	13 0
	41,256	13 0
	£106,072	9 3
INCOME.		
Gas-rental within the city—		
Private consumers	£269,761	11 2
Meter-rents	7,258	9 4
Stove-hire	444	7 9
Gas consumed in public lamps, not included £20,942 18s. 10d.		
	£277,464	8 3
Gas-rental beyond the city—		
Private consumers	£93,646	14 1
Meter-rents	3,147	1 4
Stove-hire	203	4 11
Public lamps	6,778	5 4
	103,775	5 8
	£381,239	13 11
Coke	24,845	17 7
Tar	18,645	4 9
Ammonia water	16,968	14 5
Rents	323	10 10
Balance of bankers' interest	106	18 8
Spent oxide, Droylsden station	32	8 3
	£442,362	8 5
GENERAL SUMMARY OF THE CAPITAL AND REVENUE ACCOUNTS.		
RECEIPTS.		
Balance brought forward*	£127,452	10 6
Loans received during the year	28,770	0 0
Transferred from profit and loss account for liquidation of mortgage debt	26,454	0 0
Amount of depreciation written off capital account	33,623	0 9
Balance of profit and loss account (as per statement)	41,256	13 0
	£257,556	4 3
EXPENDITURE.		
Loans repaid.	£55,305	16 0
Amount paid over to the City Fund account out of profits for the year ended March 31, 1888	23,331	0 0
Expenditure on capital account	30,624	0 9
Stocks on hand.	£76,462	3 3
Gas-rents, &c., due	143,067	15 0
Cash in Treasurer's hands	3,787	9 8
	£223,317	7 11
Less accounts, &c., owing by the Committee, deposits in hand, with interest due thereon, and balance owing to bankers	75,022	0 5
	148,295	7 6
	£257,556	4 3
* Improvement Committee (balance of contribution for the year ended March 31, 1887)		
Balance	£8,989	0 0
	127,452	10 6
Total (see Summary at March 31, 1887)	£136,441	10 6

STATEMENT OF ASSETS AND LIABILITIES.		
PERMANENT ASSETS.		
Gaythorn station—land, buildings, and apparatus, less depreciation	£195,457	9 9
Rochdale Road station—do.	251,783	15 0
Droylsden station—do.	8,960	8
Bradford Road station—do., and amount received for brick-making	408,796	12 11
Street-mains stores (Poland Street)—land, buildings, and apparatus, less depreciation	2,989	18 4
Street-mains—less depreciation	347,265	17 2
Service-pipes laid	48,008	16 4
Hired meters—less depreciation and amount received for damaged meters	74,216	13 8
Meter-proving apparatus—less depreciation	26	17 11
Lamp department—do.	8,260	13 6
Hired stoves—do., and amount received for stoves sold	4,601	5 1
Cottage property purchase-money	1,652	13 6
FLOATING ASSETS.		
Cannel, coal, retorts, and other material in stock	76,462	3 3
Gas-rents and sundry accounts due to the Committee—revenue account	143,067	15 0
Cash in Treasurer's hands	3,787	9 8
Total property and assets	£1,575,338	9 6
Profit and loss account—		
Deficiency on revenue account, March 31, 1887	£45,857	7 3
Less profit this year	17,925	13 0
	27,931	14 3
	£1,603,270	3 9
LIABILITIES.		
Mortgage debt	£759,356	13 4
Sums advanced (not secured by mortgage)	2,430	0 0
Sundry accounts owing by the Committee	25,195	8 2
Deposits in hand	30,055	16 10
Interest due on same	3,380	1 2
Cash deposits for due performance of contracts	5,050	0 0
Amount payable on account of cottage property	1,600	0 0
Balance owing to banks on revenue and extension accounts	9,740	14 3
Total liabilities	£836,808	13 9
Sinking fund, as per last report	£740,007	10 0
Transferred from profit and loss account for the year ended March 31, 1888	26,454	0 0
	766,461	10 0
(Signed) CHARLES NICKSON, Superintendent.	£1,603,270	3 9

APPENDIX A.		
Statement of the Lamp and Private Rental (including Meter and Stove Rents) for the Year ended March 31, 1888.		
Within the city—		
Private rental	£277,464	8 3
Public lamps	20,942	18 10
	£298,407	7 1
Beyond the city—		
Private rental	£96,997	0 4
Public lamps	6,778	5 4
	103,775	5 8
	£402,182	12 9
Deduct gas supplied to city lamps and not charged	20,942	18 10
Total gross rental	£381,239	13 11

APPENDIX B.				
Comparative Statement of the Gas transmitted from the Works in the Daytime and during the Twenty-four Hours.				
	DAYTIME.		TWENTY-FOUR HOURS.

[For Appendix C, see next page.]				

APPENDIX D.

This appendix consists of a table showing the number of each size of meter, and also the number of stoves, in use on March 31, 1887 and 1888, respectively. Of the first-named appliances there were fixed at the former date 77,655; at the latter, 78,084—an increase of 429. Of stoves, there were 1750 in use at the end of last March, as compared with 1609 at the corresponding date in 1887; being an increase of 141. Accompanying the table is a statement showing the number of meters on hire at the two dates above named. On March 31, 1887, it was 63,261; on March 31, 1888, it was 64,707—an increase of 1446. Of course, these figures are included in the totals already given.

APPENDIX C.

Statement showing the Results of Working, &c., at the Gas-Works from June 24, 1880, to March 31, 1888.*

Year ended June 24.	Coal and Cannel Carbonized.	Gas.						COKE MADE.		TAR MADE.		AMMONIA WATER.			
		Make.	Yield per Ton Carbonized.	Illuminating Power.	Make reduced to 20-candle Power.	20-candle Gas made per Ton.		Tons.	Cwt. per Ton Carbonized.	Tons.	Gallons per Ton Carbonized.	Make.		Make at 10-oz. Strength.	
												Gallons.	Gallons per Ton Carbonized.	Gallons.	Gallons per Ton Carbonized.

* These particulars appear in the accounts for the first time.—ED. J. G. L.

† This is a period of nine months ended March 31, 1884.

‡ From this year the figures are made up to March 31.

APPENDIX E.

Gas-Mains Laid and Taken Up during the Year.

Laid within the city	34,012 yards	
„ beyond the city	14,036 „	48,048 yards
Taken up within the city	30,838 yards	
„ beyond the city	5,805 „	36,643 „
Net increase	(or $6\frac{1}{2}$ miles 405 yards).	11,405 yards
Pipes laid prior to March 31, 1887—		
Within the city	711,657 yards	
Beyond the city	444,946 „	1,156,603 „
Total length of mains laid	(or 663 miles 248 yards).	1,168,008 yards

APPENDIX F.

This consists of a statement showing the amount of gross profit made from the gas undertaking, and the mode of its appropriation, from 1862 to March last. It is, however, sufficient here to give the figures for the past financial year, and the totals for the 26 years during which the gas supply has been in the hands of the Corporation:—

	Year ended March 31, 1888.	Total from 1862 to March 31, 1888.
Profit.	£106,072 9 3	£2,170,410 3 8
Appropriation of profit—		
Interest.	£29,832 16 11	£534,811 10 5
Liquidation of mortgage debt	26,454 0 0	660,041 10 10
Surplus.	41,256 13 0	908,711 5 1
Street lighting (gas not included)	8,528 19 4	66,845 17 4
Transferred from reserve fund	—	£29,943 17 9
Carried to reserve fund for contingencies	—	29,943 17 9
Paid over to Improvement Committee	£23,331 0 0	936,642 19 4
Borrowed money owing	761,786 13 4	—
Amount charged to revenue for depreciation	33,623 0 9	622,641 6 6
Excess of assets	738,529 15 9	—

THE PUBLIC LIGHTING OF EXMOUTH.—The Exmouth Local Board, at their meeting last Wednesday, considered a long report from a Committee appointed to deal with the subject of the defective gas supply. The Committee reported that the consumption of the gas-burners at which there were meters fluctuated greatly—from 5 to 7 feet per hour; and they recommended that a uniform rate of 5½ cubic feet per hour should be adopted forthwith, as fair to both the Company and the town. A long discussion followed between the Chairman and a Director of the Company; and the latter elicited that the irregular burning arose from lack of attention by the officers of the Board, and that it was now remedied. On the part of the Company he agreed to the recommendation.

LIVERPOOL WATER SUPPLY.—Our readers are aware that for a considerable period great inconvenience has been experienced in Liverpool, particularly in factories and other large establishments, owing to the short supply of water. The Corporation officials were compelled to resort to the expedient of restricting the hours of supply so as to prevent a water famine in the city. Their anxiety has been relieved to a great extent by the heavy rainfall of the past few weeks, which has caused a large increase in the quantity of water in stock; but the stock is now much less than it was at this time last year. At the meeting of the Water Committee of the Corporation on Monday last week, it was reported that the stock of water at Rivington had been increased to 1,280 million gallons. This was considered very satisfactory; and the Committee decided to increase the hours of supply in the city and Bootle to 12 hours per day, and in the suburban districts other than Bootle to 18 hours per day; the alteration to take effect on the following Wednesday.

THE HUDDERSFIELD CORPORATION WATER-WORKS ARBITRATION.—In the arbitration which took place some months ago between Sir J. P. P. Radcliffe, Bart., and the Huddersfield Corporation, to settle the amount payable by the Corporation for lands at Marsden, belonging to him, and taken permanently, or temporarily used, for the purpose of the Corporation water-works, the Arbitrator (Mr. J. Smith, C.E., of Bradford) has awarded to the claimant £1602. The agreement for arbitration, made before the lands were entered upon, provided that the Corporation should also pay 5 per cent. interest upon the amounts found to be due from the dates at which the various portions of land were taken and occupied. As most of the lands have been in the hands of the Corporation from 10 to 15 years, the interest will amount to upwards of £3000 more. The agreement for arbitration also provided that the Corporation should pay the whole of the costs of both parties. The valuers for the claimant estimated the sum which ought to be paid to him, exclusive of interest, as follows:—Mr. T. Fenwick, C.E., £13,845 10s. 6d.; Mr. J. Farrar, C.E., £14,980 1s. 6d.; Mr. B. S. Brindell, C.E., £14,988; and Mr. J. D. Butler, £35,750. On the other hand, the Corporation valuers made the following estimates of the amount which should be paid:—Mr. G. H. Crowther, C.E., £1649; Mr. T. Hawksley, C.E., £2873; and Mr. P. Fowler, C.E., and Mr. C. H. Marriott, C.E., agreed with the estimate of Mr. Crowther. The Counsel for the claimant in the arbitration (which occupied eight days) were Mr. E. Tindal Atkinson, Q.C., and Mr. R. W. Harper; and Mr. L. A. Kershaw and Mr. F. Mellor were Counsel for the Corporation.

YORK UNITED GAS COMPANY.

The Half-Yearly General Meeting of the Company was held last Thursday—Mr. J. F. TAYLOR in the chair.

The SECRETARY and MANAGER (Mr. C. Sellers) read the Directors' report, in which they stated that there was a balance of £9128 to the credit of the profit and loss account. This amount, after being charged with £365, the half-year's interest on the borrowed money, leaves £8762, out of which the Directors recommend the payment of the usual half-year's dividend, amounting to £6600; being at the rate of 5s. per share upon the old shares, and 4s. per share, or 5 per cent. per annum, upon the new shares. The Directors observe that the balance of revenue account for the half year is somewhat exceptional, and higher than they anticipated. This arises, they say, largely from the better prices obtained for the principal residuals, and from the fact that the Company's stocks of residuals were practically all sold, and credited in the half-year's accounts; also from the fact that the legal form of the accounts excludes the monetary values of the stocks on hand from appearing as items of debit and credit in the revenue account. They point out that the profits during the years 1886 and 1887 were below the amounts necessary to meet the dividends; and, in consequence they had to be supplemented by withdrawing nearly £3000 from the reserve fund. They have therefore transferred £1000 out of the surplus profits of the past half year back to this fund, towards meeting the withdrawals referred to. The general business of the Company maintains a steady growth; but the Directors remind the shareholders that the current half year will have to bear the reduction in the price of gas to the large consumers announced in February last. As anticipated in their last report, the Company are now carrying out some improvements to their carbonizing, condensing, and purifying plant, which will further add to the efficiency of the works.

The CHAIRMAN, in moving the adoption of the report, said he did so with very sincere pleasure and gratification. As this was the end of the financial year, the meeting was the annual as well as the half-yearly one; and they consequently had a review of the year's proceedings before them. Although the increase had only been somewhat moderate during the year—viz., 4 per cent.—yet this was so far satisfactory. He thought they would find from the balance sheet, as a whole, that the prospects and position of the Company were as good as ever, or he might say better. Mention was made in the report that the price obtained for the principal residuals had increased; but, although they had met with an advancing market, they had not had any great advance at one time, but the articles had steadily grown in value. Unfortunately, this value had previously sunk very low; but, as anticipated, a revival had taken place. Another reason he might name was the fact that the legal form of the accounts excluded the monetary values of the stocks on hand from appearing as items of debit and credit in the revenue account; and as the stocks of coke and tar, &c., were nearly all sold, and credited during the past half year, they tended naturally to increase the amount of ordinary profit during this period, leaving, of course, scarcely any stock of residuals with which to commence the current half year. He was glad to say the use of coke was gradually increasing—people were finding out that it was more economical to burn it in their stoves as the Company supplied it, than to use coal; and he was glad to find that what he predicted of coke some time ago was now being realized, and its use was becoming almost universal. It would be seen from the balance sheet that £1000 had been paid back to the reserve fund. The Company had now commenced to grant the large consumers that reduction which was announced at the last meeting; and they were supplying large consumers with gas at 2s. per 1000 feet, and the next largest at 2s. 1d. per 1000 feet. He was quite satisfied that this concession would prove of great advantage to the Company, and that it was one of the wisest steps the Directors had ever taken. He expressed a hope that the next reduction made would be to the general consumer, and that this would not be long delayed. The aim of the Directors was to make as good an article as they could, and supply it as cheaply as possible. The Directors were always on the look-out to adopt anything that would improve the quality of the gas, as well as improve the facilities for its manufacture; their anxiety being to maintain the present excellent position of the Company.

Mr. W. W. WILBERFORCE seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed the payment of the dividends mentioned in the report.

Mr. WILBERFORCE seconded the motion, and it was also carried unanimously.

The whole of the Directors were re-elected, and a vote of thanks accorded to them for their services.

The CHAIRMAN acknowledged the vote, and the proceedings closed.

OPENING OF A STORAGE RESERVOIR AT PORTISHEAD.—Some months since the Directors of the Portishead Water Company thought it necessary, in consequence of the unprecedented drought, to supplement their supply by constructing a reservoir capable of holding 1½ million gallons of water, according to plans prepared by Mr. W. Minns, of Portishead. The contract of Messrs. G. Biss and Son, of Portishead, was accepted; and this firm has carried out the whole of the works—having excavated 5000 cubic yards, and built a new retaining wall across the valley—in 34 working days. The Engineer and Directors being thoroughly satisfied with the work, Mr. W. Hall, the Senior Director, opened the inlet-valve on Saturday, the 28th ult.; and the reservoir is now rapidly filling with water.

THE PUBLIC LIGHTING OF REIGATE.

PROPOSED ADOPTION OF OIL.

At the Meeting of the Reigate Town Council on Monday, the 23rd ult.—the MAYOR (Alderman Summers) in the chair—a long discussion took place on the subject of adopting oil for the public lighting of the district. The matter came up on a report presented by the Highways and Works Committee, in which it was stated that the Town Clerk had been directed to write to the Gas Companies requesting them to modify the terms contained in their previous offers of contracting for the public lighting; and that the Surveyor should apply to the Street Lighting Company and to the Defries Safety Lamp and Oil Company for their respective terms for adapting the public lamps for lighting by oil, and lay the information before the Committee.

Alderman PYM, in moving the adoption of the report, recounted the steps that had been taken at the request of the Committee to obtain further information on the subject. He stated that Messrs. Defries and Co. (whose written offers were read by the Town Clerk) were prepared to enter into a contract for lighting the public lamps with oil for a period of three years, from sunset to sunrise, for £2 8s. per lamp; and at the expiration of that time they would be willing to contract for the work for a further period of three years at the same figure, provided oil was not higher in price; but even if it increased their maximum charge would not exceed £2 10s. per lamp. It was their opinion, however, that the price would be lower and not higher. Each lamp would hold sufficient oil to burn the full power, if necessary, for 30 hours. He pointed out that at Erith, where they had adopted oil lighting, it had resulted in a saving of 5d. on the rates.* The communication addressed to the two Gas Companies had resulted in their sending in an amended proposal. But he must remind the Council that the previous offer of the Companies was to light the public lamps for the same number of hours from sunset or one hour afterwards until midnight for £3 7s. per lamp for one year and £3 6s. for three years, and the alternative proposal the Companies now made was that they should consume gas by meter, and would require one meter to be affixed to every ten lamps. Assuming that the lamps consumed the stipulated 5 cubic feet of gas per hour, each lamp would burn in the course of the year 11,000 feet of gas; and the result would be that for gas alone the cost would be £1 18s. 6d. Then the cost of lighting, extinguishing, repairing, and painting each lamp, which had hitherto been estimated at 15s. per lamp, would bring the cost to £2 13s. 6d. per lamp. The Companies always contended that, as a matter of fact, the lamps consumed on an average more than 5 feet of gas per hour—he was told that they consumed 6 cubic feet; and if that was so, it would still further increase the charge for gas from £1 18s. 6d. to something like 45s. to 46s. per lamp. Then as the Companies required them to provide meters, they would either have to pay the rent of them or provide them at their own cost; and with regard to this question he directed the Surveyor to obtain what information he could. It would be necessary for them to obtain something like 50 columns with meters attached. It appeared from the correspondence with various firms who supplied meters, &c. (which was read by the Town Clerk at the request of the Chairman), that the cost of supplying lamps with meters attached would be altogether £4 12s. per lamp, supposing the Corporation accepted the amended offer of the Companies. Messrs. Defries offered to light the lamps for the same number of hours that they had hitherto been lighted for £2 8s. per lamp. This added to the cost of £1 15s. for providing and adapting the lamps would make a very serious item; but if they accepted the contract for the three years, the cost would be about £3 per lamp. Then if they accepted their offer for another three years at the expiration of that time, the cost would only be £2 8s. per lamp, while the lamps would be lit from sunset to sunrise, which would be double the number of hours they were lit now. His own private experience convinced him that oil lighting was cheaper than gas in the ratio of 2 to 1; in other words, it was not more than half the cost of gas. He had no motion to propose on this matter, but would leave the Council to arrive at any decision they thought proper after they had heard the correspondence.

Mr. ONLEY seconded the motion, and requested that the joint letter of the two Gas Companies should be read.

The letter, signed by the Secretary of the Reigate Gas Company (Mr. E. S. Pike) and the Secretary of the Redhill Gas Company (Mr. C. Reid) contained a copy of a resolution agreed to by both Companies, offering to supply the public lamps by meter at 3s. 6d. per 1000 cubic feet; the Corporation to find their own labour, and to be at any expense necessary for lighting, extinguishing, cleaning, and repairing the lamps.

Mr. BROWN said that on the previous occasion he proposed that the Companies should be offered £2 17s. per lamp, which he considered a very fair offer. He did not think it was necessary to go into the figures again to show how he arrived at this sum; but if they took the offer of the Companies to supply by meter at 3s. 6d. per 1000 feet, they would find that 11,000 cubic feet of gas per lamp would amount to £1 18s. 6d., and repairs, &c., were estimated at 15s. per lamp—making a total of £2 13s. 6d. He contended that the Companies' offer to supply by meter had really strengthened his case. He maintained that the offer of £2 17s. per lamp was ample, and would cover any cost incurred in lighting, extinguishing, &c. He would propose—"That the Council are unable to accept the offer of the Reigate and Redhill Gas Companies to supply the street lamps by meter, or their tenders for lighting at £3 6s. per lamp; and unless they amend the same, reducing the price to £2 17s. per lamp, on the same conditions as under the present contracts, the Surveyor arrange with Messrs. Defries and Co. to light six lamps, three in the principal streets of Reigate and Redhill, with their 30-candle power lamps for 14 nights, from sunset to sunrise, to commence on Monday, the 30th of July, to the end that the Highways and Works Committee may be in a position to make a recommendation to the next Council concerning the offer of Messrs. Defries and Co., to light the public lamps at £2 8s. the lamp by the year; that the Town Clerk write to the Gas Companies, stating that unless a reply in the affirmative is received from the Gas Companies by noon on Friday, July 27, the Council will consider that the offer has been declined."

Mr. STEER seconded the motion.

Mr. FULLER said that by adopting oil-lamps the Corporation would in the first instance have to incur an expenditure not far short of £1000 in providing new lamps; and he hardly thought Mr. Brown could be in earnest in urging that they should go to this expense. The trimming and lighting of oil-lamps in the streets would become an intolerable nuisance to pedestrians, by causing an unpleasant smell. He therefore thought it was advisable to dispose of that part of the resolution at once. He moved, as an amendment—"That the question of oil lighting for the public streets be not entertained."

Mr. BURTENSHAW seconded the amendment.

Mr. SEEX proposed as a further amendment—"That the Council offer the Gas Companies £3 3s. per lamp for three years; the conditions of lighting to be the same as under the present contracts."

Mr. BROOKS: Make it £3, and I will second it.

Mr. Fuller's amendment was then put and negatived; only the proposer and seconder voting for it. Mr. Seex's amendment was also put and lost. Subsequently, Mr. Brown's amendment was carried by 6 votes to 3.

It having been suggested that the Council might refuse to adopt the report.

Alderman BUDGEN said if anyone would move a resolution doing this, and negating the last part of Mr. Brown's motion, he would second it. It was a most unfair thing to introduce the matter of oil lighting into the motion; and a considerable want of consideration had been shown to those members of the Council who were disqualified from voting.

Eventually, the motion for the adoption of the report was put and carried.

THE WATER SUPPLY OF CROYDON.

NEW WORKS AT ADDINGTON.

In the last number of the JOURNAL, we intimated that the new works which have been constructed by the Croydon Town Council for the purpose of augmenting the supply, and also for furnishing a supply (when opportunity affords) to the higher portions of the borough which are at present served by the Lambeth Water Company, would be inaugurated on Thursday last. This was done with much *éclat*. It may be of interest, before noticing Thursday's proceedings, to give a few particulars regarding the various steps which led up to the erection of these additional works. The idea originated with the late Local Board of Health, whose powers were transferred to the Town Council by the incorporation of Croydon as a municipal borough in 1883. Croydon stands prominent among the provincial towns which first availed themselves of the sanitary powers of local government created by the Local Boards of Health Acts; and one of its primary undertakings was the remodelling of the water supply. The present engine-house, and other necessary buildings were erected, and the reservoir and water-tower constructed; but the area of supply had to be restricted—the whole of Upper Norwood and the greater part of South Norwood having to be supplied by the Lambeth Water-Works Company, at the rates charged in the other districts served by that Company. Discontent followed; and this has never passed away. From that time the local authorities have given earnest attention to the question of developing the supply; and the outcome is the great enlargement which was dedicated to the public on Thursday. Of course, a mutual agreement of transfer will have to be made between the Corporation and the Lambeth Company before the residents in the high districts (who at present pay double the rate charged in Croydon for their water) will derive any tangible benefit from the new works. Soon after the *régime* of the Corporation commenced, a Water Sub-Committee was appointed to consider the subject of the water supply. They advised that additional provision should be made; and, upon the recommendation of the experts engaged, they were requested to investigate the probabilities of procuring a permanent accession to the existing supply on the Addington Hills. Negotiations were commenced for acquiring about 4 acres of land from the Ecclesiastical Commissioners; and these were confirmed by the Town Council in February, 1884. It was found that not only was there water, but that there would be no difficulty in forming a reservoir capable of containing 5 million gallons at an elevation 91 feet higher than Upper Norwood. Professor Boyd Dawkins's reports on the scheme were very satisfactory; showing that there was here an available supply of more than a million gallons a day, without any fear of diminution. The works have been proceeding with much vigour and success since 1886; and there can be no doubt that the future will show the wisdom of this undertaking.

The following particulars of the new works, which were distributed to the visitors on Thursday, will be of interest:—The well is situated three-quarters of a mile south of Addington village, near Hares Bank. The level of the surface of it is 311 feet above sea-level. It is sunk to a depth of 200 feet, and is 10 feet in diameter, all in chalk. The lowest bed of flints or bottom of the upper chalk was passed at 152 feet from the surface. Water was first found at 87 feet from the surface; the largest yield during the sinking being about 180,000 gallons a day. Headings have been driven in several directions from the well, chiefly at a depth of 142 feet from the surface; but those on the east side have yielded the most water by crossing several important water-bearing fissures. The first of those cut through increased the pumping 600,000 gallons a day. In continuing the headings on this side, several more important fissures were cut through, yielding large supplies of water; and when the yield of the well was 2,491,000 gallons in the 24 hours, the work in the well had to cease through the inability of the pumps to keep the water down. This was in February, 1887. The total length of the headings is 813 yards, which are generally 6 feet high and 4½ feet wide. The storage capacity of these and the lower part of the well is about 502,090 gallons. The pumping machinery has been erected by Messrs. Easton and Anderson, and comprises a compound beam-engine of the Woolf type, three steel boilers, and double-acting well and lift pumps of the bucket-and-plunger pattern. The engine has a high-pressure cylinder, 20 inches diameter, and 4 feet stroke; low-pressure cylinder 34 inches diameter and 6 feet stroke. The well pump is worked from the end of the beam; and the reservoir or lift pump by a continuation of the low-pressure piston-rod under its cylinder. Both pumps are 19 inches diameter and 6 feet stroke, and deliver 72 gallons each stroke. The engine will make 18 strokes per minute; and will therefore deliver 77,760 gallons per hour. The boilers are 26 feet long and 5 feet in diameter. The working pressure of the steam is 100 lbs. per square inch. The pumps are so arranged that a duplicate set can be put in the well. Suitable buildings, consisting of engine and boiler houses, have been erected large enough to contain duplicate engine and boilers; and also two cottages for the engine driver and stoker. The reservoir is built upon the Addington Hills, which are composed of the pebbles of the Woolwich and Reading Beds. It is built entirely of concrete, without puddle backing; but it is rendered inside with neat Portland cement. The contour of the ground caused the reservoir to be narrow, the size being 420 feet by 124 feet by 16½ feet deep; and the capacity 5 million gallons. The seven covering arches, run lengthways, have a span of 16 feet with a rise of 4 feet, and rest upon walls consisting of piers and arches 2 feet thick. The outside walls are 6 feet thick at the base, and batter to 4½ feet thick at the top. The floor is 1½ feet thick. The covering arches are 1½ feet thick at the crown, and 3 feet at the springing. There is 1½ feet of earth covering over the crown of the arches. The overflow-level is the same level as the springing of the covering arches, and is 465 feet above sea level. The reservoir has a division wall 12 feet high, with arrangements for using one-half when the other one is emptied for cleaning or repairs. The overflow level is 100 feet above that of the high-level tank on Park Hill, and 86 feet above the highest road in the borough—viz., Church Road, Upper Norwood. Instruments will be used which will transmit automatically and register upon a diagram paper, and also upon a dial plate in the engine-house, the varying levels of the water in the new and old reservoirs. This is for the purpose of regulating the pumping according to the demands of the day, and will, it is said, be of great service in the management of the water-works. In regard to the mains, the pumping-main from the well to the reservoir is 21 inches in diameter and the delivery-main from the reservoir is an 18-inch

* In connection with this statement, it will be well to call our readers' attention to the letter of Mr. R. P. Keys which appears elsewhere to-day.—Ed. J. G. L.

one to Coombe Lane, down which there is a 12-inch main to the old reservoir, and along Oaks Road a 15-inch one to Upper Addiscombe Road; a 12-inch one forward to High Street, South Norwood; and a 9-inch one to All Saints' Church, Upper Norwood, with smaller mains forward to Norwood new town, in Central Hill, and other branch mains, the smallest of which are 3-inch ones. The total length laid is about 13½ miles, and 2454 tons in weight. The greatest pressure is 345 feet in Portland Road. The district for domestic supply is the area of the borough within a 2-mile radius from the Town Hall, with about 75,000 people; but the Council have power to supply the whole of the borough with water for road watering and flushing sewers. The consumption last year averaged 2,255,327 gallons per day. The supply is constant. All the works were carried out by Messrs. Kirk, Knight, and Co., of Sleaford, from the plans and under the superintendence of Mr. Thomas Walker, C.E., Borough Engineer.

The inauguration proceedings commenced on Thursday shortly after noon, when the Archbishop of Canterbury was met at the well by the Mayor (Mr. J. W. Hobbs, J.P.), the members of the Water Committee, the Town Clerk (Mr. C. M. Elborough), and the Borough Engineer. His Grace at once set in motion the engine which pumps the water from the well into the reservoir; and an enthusiastic cheer was promptly given by the visitors. The company then proceeded to the reservoir, where a large marquee had been erected. Here, by invitation of the Mayor, some 250 guests sat down to luncheon. A number of toasts were proposed and duly honoured. The Primate afterwards offered up a special supplication, alluding to the work which had been so successfully accomplished. Prayers over, His Grace opened the valves of the reservoir; and almost instantly a fountain, some 500 yards off, leaped into the air. A trumpeter signalled with a flourish the event, and the band of the First Volunteer Battalion, "The Queen's" Royal West Surrey Regiment, struck up the "National Anthem;" and shortly afterwards the large concourse of people which had assembled dispersed.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Aug. 3.

Sulphate of Ammonia.—The market partakes somewhat of a holiday appearance; and there is very little inclination all round to do business. The quantity offering remains small; and, with a probability of an increasing demand during August, there is no occasion for manufacturers to lose heart—the weaker tendency of the Leith and London markets notwithstanding. Speculators, encouraged by the continued slackness of the market, are freely offering for near and future delivery at lower prices, though the undiminished firmness of the nitrate market seems hardly to invite ventures of this kind. The position differs strangely from that of the same time last year, when sulphate was about £1 per ton dearer, and nitrate was lower; and what is more peculiar still is that no sufficient reason can be furnished for these altered conditions. The increase in the production this year appears to be less than usual; and it can hardly be said that the consumption is declining. Hull quotations are £11 12s. 6d. to £11 13s. 9d.; Leith, £11 8s. 9d. to £11 10s.

LONDON, Aug. 4.

Tar Products.—Benzole and anthracene find ready buyers, and, indeed, most of the products are in fairly good request; but there is very little business transpiring owing to the small quantities being produced. Prices have ruled generally about the same as the previous week: Tar, 15s. to 20s. per ton. Benzol, 90 per cent., 2s. 10d. per gallon; 50 per cent., 2s. 4½d. per gallon. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4d. per unit; "B" quality, 1s. 2d.

Ammonia Products.—Considerable shipments have been made during the week; and the effort to depress the advanced prices has as not so far been successful. The market is firm, and stocks are low. The following prices have been obtained during the week:—Sulphate of ammonia, £11 12s. to £11 16s. 3d. per ton, less discount. Gas liquor (5° Twaddle), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £28. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Aug. 4.]

Sulphate of Ammonia.—Advices from all parts of the country say that business in this article is not so brisk as it was a week ago, in spite of the reports of those speculators who have bought for a rise, and who seem a little bit disappointed. Prices nevertheless have not given way much, though buyers offer about 2s. 6d. per ton below what sellers are anxious to realize. The market closes with Hull at £11 13s. 9d. and £11 10s. at Leith; while Beckton is quoted at £11 15s., and London (outside makes) at £11 13s. 9d.

Tar Products.—Tar products remain in much the same condition as last week. In benzols, 90 per cent. is quoted at 2s. 10½d., and 50 90's at from 2s. 4d. to 2s. 5d.; while solvent naphtha is in great request at about 1s. 2d. Creosote is very firm, though the fancy prices at one time realized by a few dealers have been cut down by the action of one or two large makers, who are now willing to sell one or two barrels at a distance at wholesale rates. Carbolic acid (crude) is dull for the present; but better prices are looked forward to in the future. Anthracene is firm at 1s. 1½d. for "B" quality, and 1s. 4½d. for "A." Our London correspondent informs us that sales have been made of "A" quality at this price extending over the whole of next year. Pitch remains at 13s. f.o.b.; and in some instances 13s. 6d. has been realized.

MALTON GAS COMPANY.—The report of the Directors of this Company to be presented to the shareholders at their half-yearly meeting to-day shows that, in all branches, the operations of the concern in the six months ending June 30 last have been successful. The amount available for division among the shareholders, after providing for the interest on loan capital and on the reserve fund, is £1183 0s. 10d., out of which the Directors recommend the payment of a dividend at the rate of 10 per cent. per annum, free of income-tax. After payment thereof, there will remain £141 4s. 10d. to go to the next half-year's account, being £109 1s. 7d. in excess of the balance brought from the previous half year. The long-continued cold weather of the past winter and spring induced a more than usual increase in the sale of gas; the quantity sent out from the works being 1,445,000 cubic feet in excess of the corresponding six months, or an increase of over 9 per cent. The Directors have concluded an agreement with the Malton Local Board for the public lighting for a term of three years, upon a basis fair and equitable to both parties. The Manager (Mr. H. Tobey) reports the works and mains to be in thoroughly good condition.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The Corporations of Edinburgh and Leith are now in possession of the gas-supply undertakings. As stated in another column, the Commissioners became proprietors of both the local gas-works at midnight on the 31st ult.; their ownership beginning on the following day, in terms of the Act recently passed. The stocks and stores then on hand were measured by Mr. R. Mitchell in the Edinburgh Gas-Works, and by Mr. F. T. C. Linton in the Leith Works; and the gas sold since the opening of the financial year being also the property of the Companies, by arrangement, the station meters were read. It is intended that the Commissioners will draw the revenue for the period since the last collection of accounts; and, subject to the usual deduction for leakage, pay over to the Companies an amount proportionate to the quantity of gas passed out of the works within the period, calculated at the current price, which is 3s. 6d. per 1000 cubic feet. It was a condition of the transfer that the cash payments for goodwill should be made on the 1st inst.; and, after arrangement with the bank (the Commissioners not having then drawn any revenue), these liabilities were promptly met. Following this there was a more formal ceremony of handing over the works in both cases—a proceeding which was not statutory, but which was got up, no doubt, out of respect for the well-known propensity of public bodies to indulge in display. The ceremonies at the works were brief; but after them there followed a luncheon which occupied more time. It was quite apparent that there was a much stronger *rapprochement* between the Commissioners and the Edinburgh Company than between them and the Leith Company. Sir Thomas Boyd, on behalf of the Edinburgh Company, was all compliment; and Mr. Colston, on behalf of the Commissioners, echoed every sentiment. On behalf of the Leith Company, Mr. Tawse took advantage of his last opportunity to refer, in tones of evident disappointment, to the animadversions which were cast upon his Company during the negotiations; and, as if it were necessary to point it out, he called the attention of the Commissioners to the efficient condition of the works. Mr. Colston, in his acceptance of the works, spoke stiffly, and proceeded to utter a few sentences which, in the recollection of what actually took place, might have been better left unsaid. They saw from the first, he said, that it would be absolutely requisite to have both undertakings in their hands. I cannot pin the Committee to any official utterance to this effect; but in the course of last winter it was portentously given out by the organ of the Committee—evidently to frighten the Leith Company—that the Corporations were to go on with their Bill, and to enter into opposition with the Leith Company. Of course, such a thing was out of the question; Mr. Colston himself now says it. What is important in the statement of Thursday, is that the Committee are admitted to have acted with more knowledge than judgment; having been quite aware during the winter that they were occupying an untenable position.

The Commissioners have got through a great deal of work—much of it of a routine nature. They have been fortunate in securing contracts for coal at an average rate of 11s. 0½d. per ton, as compared with 14s. 7d. which was paid by the Companies last year. With this saving there ought to be a very large surplus at the end of the first twelvemonth of the Commissioners' ownership. In the meantime, they have resolved to keep the price of gas at 3s. 6d. per 1000 cubic feet, and to maintain a quality of 28 candles. But for the negotiations, I have reason to believe the price of gas would have been reduced before now. As it is, the Commissioners may be expected to be popular at the end of the year, when they announce the concessions they will be able to make. It will be some time before the work of transfer will be so far advanced as to allow of the dissolution of the two Gas Companies. There is, of course, no need to hurry this matter, except in the interests of the shareholders, some of whom may be anxious to have their share in the distribution of what is realized. Until the Companies are dissolved, their interests will require to be attended to; and I understand that it has been arranged that they will not be under the necessity of incurring charges for maintaining a staff of officials to look after their work—the Commissioners having agreed that this shall be done by the present staff.

There was a discussion in the Edinburgh Town Council last Tuesday—probably the last on the subject of the gas transfer. The subject was a small one, relating merely to the mode of electing the Commissioners—a question with which the Council had nothing to do after the election was over. The time for regulating the election was when it took place; and having once been accomplished, it could not be set aside except by judicial intercession upon proof of irregularity. The Lord Provost was slow in arriving at the above conclusion, and allowed a discussion which, had he been better advised, need not have occurred. The irregularity was started by Bailie McDonald, who only received two votes in the election. It is just probable that his complaint was more founded upon that score than upon the exclusion of the Convener of the Lighting Committee from the Gas Commission, which he put forward as the ostensible reason for his raising the question.

The Aberdeen Gas Committee have obtained a very exhaustive report from Dr. Wallace, upon the quality and capacity of the coals they have been employing in the Corporation Gas-Works; but whether they will be able to do anything with it remains to be seen. I fancy it is rather technical for most of the Commissioners. What they will be able better to explain to their constituents will be the report by the Gas Treasurer, giving the result of the investigation into the amounts realized for gas in certain thoroughfares since 1886. Taking everything into account, the explanation of the recent agitation over increased charges seems to be that the distributing plant is not in the best order, taken, probably, in connection with this—that the consumption is not conducted on the soundest principles. There may also be some necessity for altering the pressure at the works; though there is no suggestion of such being required in the report which has been submitted.

There is a probability that the domestic water-rate in Edinburgh will this year be reduced by 1d. in the £1, out of the surplus of £7000 which the Trustees have in hand from the past year. Some of the Trustees are understood to be opposed to the proposal, at a time when they are looking out for an additional supply; but it is believed by others that there are considerations which render a reduction advisable, as the wisest course to follow in the circumstances.

Reports have been received by the Perth Water Commission regarding the analysis of the water which it is proposed to utilize as an auxiliary supply. Samples were taken on the 17th of July from a pit which has been sunk in a gravel-bank to the north of Perth Bridge. Dr. Stevenson Macadam, of Edinburgh, says that the water contains a very small amount of saline matter in solution, and is decidedly soft in nature. It is free from noxious organic matters or other deleterious ingredients. In these respects, the water is of excellent quality for domestic supply. The traces of flocculent suspended matter are of vegetable origin, and would be readily removed by mechanical filtration. He had, he said, concluded that the water could be conveyed through iron mains, coated hard with pitch, and

through lead service-pipes, as well as be stored in cisterns lined with lead, without being deleteriously affected. He was therefore of opinion that the water was suitable in all its characters and properties for every human purpose—including drinking, cooking, and washing—and was well adapted for raising steam and for other manufacturing operations. Dr. Wallace, of Glasgow, reports that the filtration does not appear to be perfect; but that the water is quite satisfactory, and can easily be made all that is desired. The Commission last Thursday instructed Mr. Peattie, their Engineer, to prepare a report and plans showing how the proposed additional supply could be obtained from the place where the samples were taken.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

Many of the members of The Gas Institute who, on the occasion of the meeting in this city last summer, joined the excursion to Loch Fyne and Inverary in the famous steamer *Lord of the Isles*, will doubtless have very agreeable recollections of that pleasant outing. They may therefore feel somewhat interested in learning that the Local Committee who organized the excursion, have just presented an illuminated address to Mr. D. Newlands, the Chief Steward of the steamer, who, on that occasion most successfully catered for the physical wants of about 600 persons while the vessel was on her way to and from Inverary, their desire being to recognize in a marked manner their extreme satisfaction with the handsome way in which he discharged his onerous duties. The presentation was made to Mr. Newlands on the ordinary trip of the steamer this day week; there being present a number of gentlemen who had been attending the annual meeting of the North British Association of Gas Managers, and especially including Messrs. David Terrace, James M'Gilchrist, and R. S. Carlow.

The prospective reduction in the price of gas in Glasgow to the extent of 2d. per 1000 cubic feet, as indicated in last week's "Notes," does not seem to affect the value of the shares of the Partick, Hillhead, and Maryhill Gas Company, which is a strong rival of the Glasgow Corporation Gas Commissioners, over a large area throughout the west and north-west suburbs of the city. The ordinary shares of the Company have lately been quoted at as high as 90s.; but they subsequently declined a little, and have been sold at 85s. It is stated that preference stock cannot be obtained, even at £6 10s. per share. The Company seem to have had a good year; but it will be a little time yet before the complete details are available. An immense advantage has been gained by having a branch line from the North British Railway system through the works; and not only will the Company be able to pay up the two years' arrears of dividend to the preference shareholders of 5½ per cent. per annum, making 16½ per cent. for three years, at their next meeting, but they can also pay 2½ per cent. to the ordinary shareholders, or write off this amount for depreciation, as may be deemed most advisable. Within the past two years the works have been much improved, with a view to economy of manufacture. One of Young's patent washer-scrubbers has been put up, capable of dealing with 3 or 4 million cubic feet of gas per day; and quite lately the top framing and columns of a gasholder 100 feet in diameter by 50 feet in height have been completed by the Airdrie Iron Company. On the occasion of the recent excursion of the members of the North British Association of Gas Managers they had the opportunity of seeing the gas-works under Mr. Levi Monk's charge displaying a lot of bunting to celebrate the two events. I understand that the debenture stock of the Company has been reduced by about £10,000 during the past two years; and as the works have now been improved in value to the extent of about £12,000, the shareholders ought to be satisfied. If they do not get dividends, they have the gratification, at all events, of knowing that their stock has been improved in its market value from 37s. 6d. to 85s. per share; and as the arrears of preference dividend and balance of the old debt will now be paid off, while the works are in better order, Mr. Monk considers that he begins the new financial year about £4000 better than the past year was commenced.

There is still a hitch in connection with the payment for the gas burnt at many of the stalls in the International Exhibition. Some time ago there was a conference between certain members of the Corporation Gas Committee and representatives of the Lighting Committee of the Exhibition with reference to the accounts that were then said to be due for gas consumed at the exhibition; and an understanding was come to that all gas that had been used for motive power and for lighting should be charged to the Exhibition Committee, and that accounts for gas employed for all other purposes should be charged to the exhibitors themselves. Still, as I have said, a hitch continues, as a number of the exhibitors consider that they have a grievance. They allege that in the original exhibition prospectus it was stated that steam, gas, and water would be supplied free to the exhibitors; and they complain at the Gas Trust officials serving them with notifications that their supply of gas will be cut off if that which has already been consumed be not paid for within two days. One of them, who has a stall in the Machinery Court, has closed it; and the reason he gives for doing so is that his supply of gas has been stopped. Of course, what are regarded as being strictly within the class of "gas exhibits" are supplied with free gas by the Exhibition Committee, who will pay for it on the footing that in similar cases they provide water or steam, or both.

On Thursday night the annual general meeting of the Carlisle Gas Company was held—Dr. Selkirk, Chairman of the Company, presiding. The report and balance-sheet for the past year were read and approved, and the dividend was fixed (as usual) at 7½ per cent., or 6s. per share. It was agreed to reduce the price of gas from 4s. 2d. to 3s. 9d. per 1000 cubic feet. The Company supply (without any additional charge to the inhabitants) the gas for the street lamps, and bear the cost of lighting them and all other incidental expenses connected therewith, as well as the gas for the town clock.

At the Hamilton Town Council meeting on Thursday evening, on the recommendation of the Gas Committee, it was agreed to accept of the offer of Messrs. W. G. Walker and Son, of Ayr, for the secondary products. In moving the adoption of the report, the Convener (Baillie Archibald) mentioned that the offer for the tar and liquor exceeded that of last year; and that the revenue from this source in the coming year was expected to be in excess of that of the past year to the extent of £100.

The Glasgow pig iron warrant market has been very active this week; a rather large business having been done. For the time being storing has stopped—indeed, 75 tons have actually been taken out of the public warrant stores. A fairly large legitimate business is passing. On Monday the price of Scotch pig iron went up to 39s. 10d. per ton, cash; but on the execution of a large selling order, the price receded to 39s. 4d., and the close was 39s. 6d. per ton. The market on the following day was rather weak; the closing price being 39s. 4½d. per ton. Some fluctuation took place both on Wednesday and Thursday; and the price declined on Friday to 38s. 11d. cash. During the week the price of Cleveland and hematite iron has in each case declined 6d. per ton.

No very material change has taken place in the condition of the coal trade; but prices are certainly hardening in almost all departments.

A BANKRUPT MINING ENGINEER AND MR. S. HUNTER'S COMMISSION.—At the Nottingham Bankruptcy Court last Friday, the case of Mr. William Smethurst, mining engineer, formerly of Wigan, but recently residing in Nottingham, came before his Honour Judge Bristowe, Q.C. Mr. Hincks, who appeared for the debtor, made a statement as to Smethurst's negotiations with Mr. S. Hunter for the supply of coal to the Salford Corporation. The debtor explained that, as Manager of the Garswood Colliery, he sold coal to Hunter at 8s. a ton; but the coal was invoiced to the Corporation at 9s. 6d., and the difference of 1s. 6d. per ton was received by Hunter. He denied that any part of the 1s. 6d. went to pay off any of his liabilities. The contract which he had made with Hunter was continued by the new Company, which took over the colliery. The debtor was allowed to pass his examination.

THE NEW WATER-WORKS OF THE ST. HELEN'S CORPORATION.—The new water-works which the St. Helen's Corporation have been carrying out for the past few years, under the powers of an Act obtained by them in 1882, entered upon their final stage last Tuesday, when the Mayor (Alderman M'Kechnie) laid the foundation-stone of the new pumping station at Kirkby, in the presence of a large number of the members of the Council and the borough officials. The St. Helen's water district extends over 12,000 acres. The population within this area is estimated at about 68,000; and the daily consumption of water averaged in 1877 2½ million gallons. When this is compared with the quantity of water that it is estimated will be yielded when the scheme is completed—6 million gallons per day of 24 hours—it will be at once evident that the supply will be one of the best and most satisfactory that any borough could possess.

THE NORTHERN COAL TRADE.—The demand for coal shows a slight increase, though deliveries of gas coal have been lessened by the delay which the storms in the South brought about. Steam coal is in favour request at from 7s. 6d. to 7s. 9d. per ton; and there is every probability of a continuance of a large demand for this and the next month. There are increased applications for gas coal both for local and more distant requirements; and now that August is well entered into, we must expect a growth of the demand regularly. Generally, the gas companies are using more coal year by year; and they are inclining to take more coal in the early autumn, as all the signs of the freight market are in favour of higher rates for sea carriage of coal in a short time. Household coal is dull. There is a good inquiry for manufacturing fuel; and when contracts expire the tendency is to ask higher prices for renewal. The briskness in the iron trade takes up more coal of this class, and may drive up prices in the winter.

† Next dividend will be at this rate.

THE EXTENSION OF THE WILTON GAS-WORKS.—The Town Council of Wilton have accepted the tender of Messrs. Edward Cockey and Sons Limited, of Frome, for the alterations and extensions at their gas-works, on which, it may be remembered, they have been advised by Mr. N. H. Humphrys, Assoc. M. Inst. C.E., of Salisbury.

THE PUBLIC LIGHTING OF UXBRIDGE.—At the meeting of the Uxbridge Local Board last Tuesday, some discussion took place on the subject of adopting oil for the public lamps. Reference was made to the proceedings of the Erith Local Board in regard to the lighting of their district; and it was decided to make a trial of an oil-lamp to be supplied by the firm who have taken up the Erith lighting.

SALES OF SHARES.—On Friday, the 27th ult., Mr. W. F. Fox submitted to a numerous company, at Ossett, several lots of gas stock, which all commanded high prices. Sixty £5 "A" shares in the *Ossett Gas Company*, offered in lots of 20, were knocked down at £13 7s. 6d. each; and fifty £5 "B" shares in the same Company, in one lot, at £10 12s. 6d. per share.—Fifty-five fully-paid £20 shares in the *Gravesend and Milton Gas Company* have just changed hands at £44 per share. For some years past those shares have realized a dividend of 10 per cent. per annum.—Last Thursday, Messrs. Blake, Haddock, and Carpenter sold at Croydon 171 fully-paid up shares in the *Croydon Commercial Gas Company*, in 25 lots. The first three lots each consisted of five £5 shares of first capital, on which dividends have been paid at the rate of 13 per cent.; and these were sold at £13 17s. 6d., £13 15s., and £13 12s. 6d. per share respectively. Lots 4 to 7 each comprised five shares of £5 each second capital, bearing the same dividend as the former, and were sold at £13 10s. per share. Lots 8 to 13 were each comprised of five shares, "A" 1871 capital, £5 each, earning the same dividend, and were sold at £13 10s. per share. Lots 14 to 21, each consisting of 10 shares, third capital, £5 each, on which dividends have been paid at 10 per cent., were all sold at £10 10s. per share. Lot 22, comprised five shares, "B" 1876 capital, £5 each, and lot 23, eight shares, all bearing 10 per cent. dividend; and these were sold at £10 10s. Lots 24 and 25, each consisting of six shares of £10 each, fourth capital, realized £20 10s.

SKIPTON WATER SUPPLY.—At a meeting of the Skipton Local Board held last Friday, a letter was read from Mr. Hill, the Board's Engineer, stating that he would propose a scheme for bringing the water in pipes from Cawder Gill into the present reservoir, in accordance with the resolution of the Board; but the proposal must not be assumed as having his approval, or as being based upon any of his recommendations. The Board decided to wait until Mr. Hill had sent in the scheme required before discussing the matter.

REDUCTIONS IN PRICE.—The *Northfleet and Greenhithe Gas Company* have reduced the price of gas in their district from 4s. to 3s. 9d. per 1000 cubic feet.—The Directors of the *Kingston Gas Company* have resolved to reduce the price of gas to 3s. per 1000 cubic feet, to take effect on the Michaelmas accounts.—The *Leyland and Farington Gas Company* have reduced the price of gas from 4s. 6d. to 4s. per 1000 cubic feet, less 2d. per 1000 feet for prompt payment. They have also reduced the meter-rent from 2s. 10d. to 2s. 4d. per annum.

THE MANAGEMENT OF THE WARRINGTON GAS-WORKS.—The minutes which the Gas Committee will present at the meeting of the Warrington Town Council this week include the following resolution:—"The Gas Committee, having received the amendment passed by the Town Council relative to the report presented by them, and considering that it is a direct vote of want of confidence in them, the following members of the Committee hereby tender their resignations:—Aldermen Holmes, Webster, Pickmere, and Chandley; Councillors Barker, Greening, Roberts, and Wright." Two members—Aldermen Harrison and Davies—do not resign. Mr. J. Paterson, F.G.S., retired from the management of the works on the 6th ult., and was succeeded on that date by Mr. Spence Haddock. The following letter from the late Engineer, dated the 6th of July, and addressed to the members of the Gas Committee, appears on the minutes:—"Gentlemen,—I feel that I cannot leave without conveying to you my very cordial thanks for many past favours, and my best wishes for your future prosperity. I regret I cannot accede to the conditions imposed by the Town Council, and venture to hope my refusal will not inconvenience you.—Faithfully yours, James Paterson."

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,

ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS &c., &c.

Catalogues and Testimonials on application at the above address.

OXIDE OF IRON.

THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 350,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 161 to 163, Palmerston Buildings, Old Broad Street, LONDON, E.C.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, 158, Palmerston Buildings, Old Broad Street, LONDON, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTCH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 30, St. Andrew Square, EDINBURGH, Scotland. No. 54, BERNARD STREET, LEITH.

SULPHURIC ACID, B.O.V., for Sulphate of Ammonia Making. Guaranteed clear, of full strength, and to produce a fine white-coloured salt. Delivered in earbays or railway tank waggons.

For prices and terms address BALE, BAKER, AND CO., 120 & 121, Newgate Street, LONDON.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE AND CO., 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56,

MILLBANK STREET, LONDON, S.W. [Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other

Gauges, &c., &c.

* * See Advertisement on Page III. of the Wrapper of last week's issue.

W. C. HOLMES & Co., Huddersfield,

AND 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings.

* * See Advertisement p. 265 of this week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas-

Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham.

Analysis of Coal, Oxide, and all Gas Materials.

GAS-WORKS of any magnitude leased, at premiums ranging from 5 to 10 per cent., according to the size of the Works. Gas-Works erected or re-modelled upon the most modern principles.

Address GEORGE WELLER, Gas Engineer, St. Ives CORNWALL.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

TUBES.

FOR Gas, Steam, and Water; Galvanized White Enamelled, and Hydraulic Tubes and Coils JOHN SPENCER, Globe Tube Works, WEDNESBURY and 14, Great St. Thomas Apostle, LONDON.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

OLPHERT'S Natural Oxide of Iron—

SUPERIOR IRISH BOG ORE (obtained from the finest estates in Ireland)—is now VERY LARGELY and SUCCESSFULLY USED for Gas Purification.

The sole representative for selling this Oxide is A. C. FRASER (late Gas Engineer at Bolton). Bridgewater Chambers, Brown Street, MANCHESTER.

SULPHURIC ACID.

HUGH WALLACE & CO., Chemical Manufacturers (the old-established firm), supply the above, which is specially adapted for making White Sulphate of Ammonia. The latter purchased in any quantities at highest market prices, or contracts for the year.

For price and terms apply Botolph House, Eastcheap LONDON, E.C.

TUESDAY, AUGUST 14, 1888.

THE IDEAL OF GAS SUPPLY.

THE members of the North British Association of Gas Managers were edified and amused at their last meeting by an interesting paper contributed by Mr. J. M'Gilchrist, which will be found in another column. The paper is not at all technical; and the author's enemies, if he has any, might say that it is not very profound, and contains nothing new. On the other hand, it expresses a number of homely truths concerning the business of gas supply, which, although they may be as familiar as the Ten Commandments, will, like them, need to be repeated a good many times yet before they are generally carried into practice. Mr. M'Gilchrist began his observations with an acknowledgment of the fact that gas has competitors in electric lights at one end of the scale, and cheap mineral oils at the other;

and the motive of his discourse was to describe the means whereby the sellers of gas may most effectually maintain their position in face of their rivals. It is here that the reproach of want of novelty first applies to the paper. The subject of the rivalry of electric lighting and oil with gas is a very much hackneyed one. It lends itself to the not very incisive style of oratory commonly affected by Chairmen of Gas Companies when addressing shareholders assembled in general meeting; and hence the mere announcement that this is the matter of Mr. M'Gilchrist's composition will be almost sufficient to cause many of our readers to turn away from it. For all that, and notwithstanding the lack of novelty not only in the subject, but also in the author's treatment of it, we make bold to say that Mr. M'Gilchrist's paper is worth reading—why and how, it shall be our business to point out in the course of this article. It was undoubtedly wise in the author to refrain from attempting to make his paper a kind of prose epic of coal gas, extolling its peculiar advantages, and decrying its rivals. He could not help doing a little in this line; and his remarks upon this head are sensible enough on the whole. There is, however, a smack of Scotch "wut" about some of these observations, which it is rather difficult for all readers to properly relish. What, for example, is meant by the assertion that some people cannot properly enjoy themselves "in company" until the gas is lighted? The author "in all seriousness," as he says, appears to imply the existence in gas—especially, it may be presumed, Scotch gas—of a peculiar exhilarating quality, which makes it, in this respect, something like Scotch whiskey. Now, we never should have suspected that any Scotsman, especially among Mr. M'Gilchrist's acquaintances, would betray this sensitiveness regarding the means whereby their evening amusements might be illuminated. Given the right ingredients and accompaniments, we should have thought that all means of lighting, from Luna's lamp to the humble tallow dip, were indifferent to the countrymen of Burns. Surely, when "Wullie brew'd a peck o' maut," no consideration of this kind was permitted to interfere with the joviality that ensued; and it would be a melancholy effect of increasing culture if the conditions of conviviality beyond the Tweed had so gravely altered as Mr. M'Gilchrist would have us believe.

Mr. M'Gilchrist's principal task, however, was to set forth the conditions under which an ideal Gas Company might best cope with the requirements of the age. He began this portion of his work with a little special pleading which must not be allowed to pass unquestioned. He laid down the proposition that the satisfaction of consumers is always assured by the supply of gas of the highest possible illuminating power. Now, this is a transparent fallacy. The author's reputation for consistency was served by his upholding it on the present occasion, seeing that he has maintained the same view at other times; but the argument, as such, will not hold water. We do not intend to take up the gauntlet thus thrown down by Mr. M'Gilchrist, and to fight once more the cause of those who maintain that the extraordinarily high nominal illuminating power claimed to be supplied by gas makers in some Scotch towns is a delusion. Let it suffice to say that the argument is bad in connection with the present question. It is bad because, in the first place, it would limit the possibility of retaining gas in public favour to a very small area of the earth's surface—to wit, that portion of North Britain where the richest varieties of cannel coal can be used commercially by gas makers, to the exclusion of other material, and where the loss of hydrocarbons by condensation in street syphons may be regarded with equanimity by the Gas Companies. Secondly, the argument is bad in fact, because the history of gas agitations shows that people are not to be deterred from complaining of bad gas by any consideration of the nominal illuminating power ascribed to it by the makers. It would not be difficult to cite many examples of bitter complaining on the part of consumers and ratepayers in places where, according to Mr. M'Gilchrist, everybody ought to be perfectly happy on this score. We make these remarks, the truth of which cannot be gainsaid, in order to show that cannel gas is not the *summum bonum*, as Mr. M'Gilchrist would have the world to believe. The doctrine is all very well for the neighbourhood of Dumbarton, but it will not bear exportation; and in all probability its expounder in the present instance would drop it, should circumstances remove him into a different locality.

For the rest Mr. M'Gilchrist advocates, and very sensibly, a general *rapprochement* of the methods of selling gas to those

followed in connection with other commodities not protected by complete or *quasi* monopoly. In this view he will find more to agree with than to find fault with him. His remarks upon canvassing for custom, and similar matters, are to the point; and it is to be hoped that, when next he speaks upon this subject, he may be able to cite more examples than that of Nairn, which he selects for honourable mention. Dumbarton, for instance, cannot be so dissimilar from other towns as to prevent the gas manager from practising in it what he preaches. Meter-rents, unquestionably, are a relic of another and a different age, and should be dropped. We do not clearly understand the application of Mr. M'Gilchrist's theory respecting deposits, in connection with any practicable "co-operative" system, and think he will do well to write another paper elaborating his suggestion. There have been many proposals for placing the business of gas supply upon a co-operative footing; but, apart from the sliding scale, we do not recall any that are really worth talking about. The sliding scale is truly a co-operative system, because it gives the consumers, as a rule, two-thirds of all extra profits, and only then enables the suppliers to take the remaining third if they choose. This is co-operation of a very high order; and if Mr. M'Gilchrist has anything better to suggest, we shall be glad to hear from him.

The question of internal fittings is the key of the problem of rendering gas lighting popular among the poor, and it is one to which Mr. M'Gilchrist and other gas managers who may be desirous of extending the consumption of gas among the people who now burn oil may devote their best attention. It is easy to propound generalities upon this vital subject; but hard to get a firm grip of the matter, and harder to carry good measures into practice. One is tired of listening to protestations of good-will from gas officials with relation to this vexed question, while so little is being done to deal with it even tentatively. When a congress of gas managers who have had experience of retailing gas in small quantities in different parts of the kingdom meets for the comparison of notes and the interchange of counsel, it may be possible to say something fresh upon the subject by way of comment; but until that day, which seems to be far distant, there is nothing to be remarked upon it except to lament that what everybody admits to be desirable in the abstract is realized even in part by so few.

In conclusion, we may be permitted to observe that, again like the Decalogue, Mr. M'Gilchrist's ideal is already fairly realized in different examples. With but little exception, all his programme may be found in force in various localities. There are some towns wherein the highest quality of gas that can be made from cannel coal is to be had; some where the gas is cheap; some where it is as pure as chemical science can make it; others where canvassers are employed; others, again, where fittings are supplied on hire, rentals collected at short intervals, meter-rents not charged, and the other points of Mr. M'Gilchrist's charter in full force. There are, as he admits, towns where the Corporation do not take money out of the pockets of gas consumers to pay rates; but these are not so many as might be desired. As to rating gas undertakings fairly, that is one of the great exceptions which prove the rest of the statement. The problem appears to be to combine all these good points in one example, and afterwards in all. It is like the problem of humanity. There is enough good scattered among men to make an ideal man, if we could get it all together. To this end evolution tends, with slow advance and many backslidings; but until it is reached, the efforts of those who desire it must be regular, persistent, and practical.

THE MEETING OF THE GASLIGHT AND COKE COMPANY.

The half-yearly general meeting of The Gaslight and Coke Company was held last Friday; and the proceedings will be found reported in full, as usual, in another column. They are not of a very interesting character. The Governor (Colonel Makins, M.P.) made the conventional speech—going through all the entries in the accounts one by one, and comparing them with the amounts for the corresponding period of last year. This is always a tedious process, and strikes us as particularly superfluous in the case of the Chartered accounts, since all the entries are comparable at a glance with the previous year's returns printed in the margin. It is customary, however, for Chairmen of Gas Companies to treat meetings of proprietors as though none of the company could be trusted to do a mental subtraction sum; and Colonel Makins is far too good a Conservative to break in upon such time-honoured usage. For all his show of careful

explanation of the accounts, however, Colonel Makins left his hearers wholly in the dark with regard to that important question which everybody who is at all interested in the Company has been asking ever since the Directors' preliminary notification of the rate of dividend and amount of the balance to be carried forward was sent to the newspapers. He said something in the course of his address about the Board not being in the habit of reducing the price of gas by "leaps and bounds." But that is precisely what they have done; and it is the very reason why criticism has grown helpless in face of the Company's accounts. Nobody outside Horseferry Road—and not very many inside that establishment—can feel much confidence in predicting anything respecting the immediate future of the Company, as a matter of accounts. There is, of course, a general idea that the Company is "all right;" but nobody can go beyond this and declare, with any approach to certainty, whether by this time next year the undivided balance will be increased to a million, or be eaten into to make up dividend, or at what price the Board may think fit to sell gas. It is significant that not one proprietor echoed the Governor's expressions of congratulation upon the excellence of the statement submitted by the Board; probably for the reason that nobody pretends to have any understanding in the matter. The proprietors take what the Board are pleased to give them, and none of them care about the accounts. The proceedings were enlivened by the inevitable bit of word-fencing between the Governor and Mr. George Livesey. As Mr. Livesey says, Colonel Makins cannot leave him alone. The Governor peers over the table to see if Mr. Livesey is present among the shareholders; and then he deliberately stirs him up by some *ex parte* statement relating to "our neighbours 'across the river,'" which he knows will bring the Chairman of the South Metropolitan Company on his legs. This time Colonel Makins touched up his brother Chairman upon the subject of the dealings of the Metropolitan Board of Works with the two Companies, and also with reference to the litigation mentioned in the report. As usual, Mr. Livesey proved well able to take care of himself and his Company. We have had on previous occasions to remark the unfortunate propensity sometimes displayed by Colonel Makins for saying ungracious and irritating things. He has managed to avoid this failing for the last meeting or two; his last error in this line being the declaration, when the movement for the abolition of the London Coal Dues was only beginning, that the question was insignificant to the Company. We do not believe that Colonel Makins wishes to stand in a bad light in the public eye; but why *will* he say such things as he did on Friday, when sneering at the project to give the public the benefit of the remission of the dues as being "philanthropy, 'which is not business?'" It is so easy not to pose as a grasping monopolist, that any Chairman of a Gas Company who goes out of his way to incur this reproach displays lamentable want of tact, to say the least. Again, to respond to Mr. Livesey's observations upon the lawsuit between the two Companies by saying in effect that the South Metropolitan Company must own to being in the wrong, apologize, and pay all costs before the Chartered Board will meet them in a friendly spirit, is not the best way of dealing with such a question. Colonel Makins claims that his side have gone to law because they think they are right; but he never seems to realize that the other party may be defending themselves for precisely the same reason, and with quite as much justification. This, however, is a comparatively small matter; for, as between two Gas Companies in litigation, an ungracious remark or two from either side is not likely to offend the public very seriously. It is to be feared that such cynical observations as those which Colonel Makins unfortunately permitted himself to make with regard to the effect of the abolition of the coal dues will rankle in the minds of those with whom the Company which he represents have every interest in keeping on the most amicable terms; and we therefore think that his conduct in this respect on Friday deserves, as the candid statesman confessed, to be characterized as "worse than a crime—it was a blunder."

HOLIDAYS FOR THE BIRMINGHAM GAS STOKERS.

The Birmingham Town Council had a field-day last week, when sundry matters connected with the administration of the Gas Department occupied the attention of the local Parliament for five hours; and an amount of talking was done in the Council Chamber which drew down upon the perpetrators the censure of the overtaxed local press. We have already had occasion to point out that the situation of the Birmingham Gas Department cannot be rightly under-

stood without an acquaintance with local politics, to which an outsider cannot pretend, or, if he did, could not profitably meddle with. Hence we cannot say for certain why the Gas Committee wished to refer to the General Purposes Committee the question of granting holidays to the workmen employed in carbonizing, instead of dealing with it themselves. As a matter of fact, it seems to have been the general idea of the members of the Town Council that the Gas Committee should attend to this among their other business; and so, after a great deal of discussion, the matter was referred back to them, with the consent of the leading members of the Committee. It was stated that the Committee desired that something like a general principle with regard to the holidays of Corporation workmen should be stated by the General Purposes Committee—a principle to which all the departments could conform. There is, of course, much to be said in favour of this view of the subject, for it can be easily understood that harmony among the various departments of the same Corporation must be a desideratum, and also that nothing is more likely to destroy this general agreement than conflicting practices in the treatment of workmen by the different Committees. At the same time, it appears to us, rightly or wrongly, that this idea of the unity of Corporation administration may be pushed to such an extreme that practical injustice may follow. Thus, while there is truth in the proposition that the workmen of the Birmingham Gas Department are paid by the ratepayers, like those of the Water or the Health Department, yet every department is not less truly to be regarded as a concern by itself, to be administered according to its own laws and necessities. It can scarcely be disputed that the custom of giving a week's holiday in the year to stokers and other gas workmen is a good and desirable one; and we cannot see that its quality suffers from the non-existence of any similar custom in other undertakings, even though belonging to the same ownership. Rather, we should say, let the Gas Department show the example, if a precedent is needed; and the others would "follow suit" as rapidly as their circumstances permitted. We make these observations in the interest of the gas workmen and of those of their superiors who desire to take the proper course in this matter, and are more particularly concerned to state the question fairly, upon the highest grounds, because, in the course of the debate in the Council upon the subject, Mr. Bishop, the Chairman of the Gas Committee, seems, according to the newspaper reports, to have fallen back, by way of opposition, upon the plea that to give the stokers their holiday would cost £1000 a year, which he appeared to adduce as a very serious consideration. We should be sorry to think that the Birmingham ratepayers are so grasping as to adopt this idea. We do not desire to attribute to Mr. Bishop any sympathy with the objection which he stated. He may have mentioned it simply in order that the Council and the ratepayers should know what are the circumstances of the case, and to prevent anybody from saying afterwards that he did not understand the conditions. The question having been left to be settled by the Gas Committee, they dealt with it in a perfectly satisfactory manner. The debate concluded with one of the attacks upon the Gas Committee and their chief officials to which the local public are growing accustomed, and which, knowing the quarter whence they proceed, they are probably able to appreciate at their true value.

At the ordinary general meeting of the Wandsworth and Putney Gas Company held last Tuesday, Mr. A. G. Hounsham was unanimously elected Auditor in the place of Mr. Johnstone, deceased, who had filled the office for the long period of 43 years.

The summer meeting of the Institution of Mechanical Engineers was opened in Trinity College, Dublin, last Tuesday week, under the presidency of Mr. E. H. Carbutt. After the preliminary proceedings, the President delivered an address, dealing mainly with the growth of Ireland. At its close, several papers were read, and discussions followed; after which the visitors were entertained at luncheon. In the afternoon there was an excursion down Dublin Bay; and the day concluded with a dinner at the Royal University Buildings. On the following day the reading of papers was resumed; and this occupied the morning. After luncheon various excursions were made; one being to the Valley of Glensmoel, where the supply of water for the city is derived from the Rathmines and Rathgar Water-Works. In the evening a *conversazione* was held by the Local Committee in the Royal Irish Academy. By the courtesy of the Lord Mayor, the Mansion House was also opened to the visitors; and dancing was kept up till a late hour. On the following Thursday the members paid a visit to Belfast, where they spent the rest of the week; an inspection on Friday of the New Island lighthouse, where Mr. Wigham's system of gas lighting is in use, being an interesting feature of the proceedings.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 306.)

BUSINESS on the Stock Exchange during the past week has naturally been restricted, owing to the interference of the Bank Holiday on Monday. But there was no tendency in prices to droop; the balance of influences being, on the whole, decidedly favourable, aided by fine weather and political calms. The Gas Department has been decidedly quiet; and very little business has been done in any but the two large issues, Gaslight "A" and Imperial Continental. The recovery in the former from its sudden depression, signs of which we noted last week, made further progress; and the quotation shows a rise of $1\frac{1}{2}$. The stock closed firm; the last transaction being at the best price marked in the week—256 $\frac{1}{2}$. The Company's meeting on Friday was quiet and satisfactory, and what then transpired should be reassuring. The accounts of the South Metropolitan Company are out, and are a gratifying financial history of the past half year. The Company's stocks, however, have not moved, nor has a single transaction in them been marked throughout the week. The interest evoked by the fortunes of gas undertakings in the Metropolis will be complete when the Commercial Company's accounts are published. We shall be prepared to find that, owing to the nascent revival of trade in the east of London, and to other causes, the Company will be able to issue a statement of figures thoroughly satisfactory to the proprietors, and to all who take an interest in the well-being of the Metropolitan Gas business, in respect of a fair increase in the consumption of gas as well as in sales of residuals. There is no move in the position of the Company's stocks. Imperial Continental is very steady—pretty well the same prices being marked every day. Some of the other Foreign undertakings have made slight advances; Continental Union old and European new being $\frac{1}{2}$ better, and Cagliari is quoted *ex div.* at the previous price. The Water Department continues very inactive; but the upward move is still in action, and has made larger strides—Southwark $7\frac{1}{2}$ per cents. having risen 6, and New River 4. The Bank rate, after standing at $2\frac{1}{2}$ per cent. for nine weeks, was raised on Thursday to 3 per cent.

The daily market movements were: On Tuesday, Gaslight "A" and Imperial Continental were active; but hardly anything else was noticed. Water was quite stagnant. Gas was quieter but firm on Wednesday; Gaslight "A" advancing $1\frac{1}{2}$. Water was as before. On Thursday, business in Gas was very restricted; but Water was a shade better. Chelsea rose 1; New River, 4; and Southwark $7\frac{1}{2}$ per cents., 6. There was a shade more animation in Gas on Friday; and Continental Union advanced $\frac{1}{2}$. In Water, Kent was 2 higher; and East London, 1. Saturday's business was extremely restricted in all departments. Gas was quiet, but very firm. European new rose $\frac{1}{2}$. Water was quite featureless; and quotations were unchanged.

ELECTRIC LIGHTING MEMORANDA.

THE MAXIM-WESTON COMPANY UNDER NEW MANAGEMENT—AN IDLE COMPLAINT —THE EFFECT OF ARTIFICIAL LIGHTING UPON WATER COLOURS—THE NEW GULCHER COMPANY.

THE changes in connection with the management of the Maxim-Weston Electric Company, which have on several occasions recently furnished matter for comment in this column, have at last culminated in the retirement of Mr. Hugh Watt, M.P., the late Chairman and Managing Director, and the termination by the new Board of the engagement of the Secretary. A new Secretary, a member of a firm of chartered accountants, has been appointed; and the true financial position of the Company will therefore in all probability be discovered and announced on an early date. All this is important matter in respect of the position of electric lighting in this country, for the Maxim-Weston Company have been one of the few surviving rivals of the great Brush Company; and either their removal or rehabilitation in a business way would affect the prospects of this concern. At present it is impossible to say what the condition of the Maxim-Weston Company really is. The two inventors whose names supply the Company's title are deservedly respected as being those of two of the cleverest electricians of the age; and it is generally understood that the Company have at their command as good a system, or systems, of lighting, both with arc and incandescent lamps, as there are at present in the market. Their troubles, however, illustrate the truth that something more than technical excellence is wanted to make electric lighting commercially profitable; and while nobody likes to see good work go without proper remuneration, the history of the Maxim-Weston speculation is full of teaching to those who hold that the day of commercial success has not yet dawned for electric lighting in England. It remains to be seen whether the removal of the old administration will save the Company; but our own idea upon the subject is that the reform of the management will not have all the effect in this direction that some of the more sanguine among the shareholders seem to believe.

Matters must be very stagnant in the electric lighting business; for our contemporary the *Electrical Review* is driven to give the place of honour in its last issue to an elaborate criticism of a specification for wiring an electric light installation in London, the greater part of which is very "small beer" indeed. The various safeguards insisted upon by the electrical engineer who drew up the specification in question are ridiculed in language which is no

always dignified, and the whole tirade runs into nearly five columns of letterpress. One would think that a better punishment of any engineer who should make himself so utterly absurd as the victim of this long complaint appears to have done would be for every respectable firm of contractors to refuse to tender for the work. Our contemporary thinks differently, however, and drives home its reproaches with a reference to the happier circumstances of the gas-fitting trade. One of the obligations complained of in the offending specification is that it shall conform to the requirements of the electrician of the Phoenix and other fire offices, who, as is well known, has drawn up rules for this class of work. We are gravely told, on the authority of "one of the largest gas-fitters in the Metropolis," that gas-fitting is never subjected to fire insurance inspection; and the same authority is "firmly of the opinion that had gas been vigorously confined to the petty restriction that now seems likely to be bound round the electric lighting industry more tightly than ever, it would not at the present moment be holding such a prominent place amongst the essential necessities of the world." This is the veriest trifling. If electric light wires had never set anything on fire, there would not have been any occasion for the fire offices to take cognizance of the way in which they are fitted. As they have done this again and again, and will probably do so a good many times in the future, it is idle to complain of the fire offices for declining to take risks unless their regulations are complied with, or of consulting engineers for insisting on their clients' interest being properly safeguarded in this respect. The reference to the case of gas-fittings is childish. When gas was first introduced, it was popularly thought that the pipes which conveyed it into houses must be hot; and the gas-fitting of the Old Houses of Parliament was originally arranged in accordance with this view. The fathers of the gas-fitting art did not waste their breath in objections to what they knew were stupid regulations, but obeyed them, charged accordingly, and left the truth to be revealed by experience. So the electricians should do; and if they are maligned by over-nervous engineers, time will show who is in the right.

A report by Dr. Russell, F.R.S., and Captain Abney, R.E., F.R.S., on the effect of artificial and natural light upon the tints of the water-colour paintings in the National Collection at South Kensington has been issued as a blue-book, and contains much interesting matter for artists, owners of pictures, and lighting engineers. The South Kensington picture galleries are well lighted at night, by both kinds of electric lamps, and also by gas; and the report of the experts, based upon experiments, is very reassuring with respect to all the systems of artificial lighting in use. Taking the amount of fading of test colours exposed to direct sunshine from May to August as the standard, it is shown that, under the usual conditions of lighting by day in these galleries, at least 100 years would be required to produce a similar effect. With gas or incandescent lamps at least 2000 years of continuous illumination would be necessary for the same result; and with arc lamps it might be produced in 200 years. It should be concluded from this statement, which is made on the highest obtainable authority, that the public art treasures in water colour are perfectly safe as exhibited under the ordinary conditions of illumination.

By dint of great exertions, the sum of £12,000 in preference shares has been raised for enabling the reconstituted Gulcher Electric Light and Power Company to commence business afresh. As £20,000 was needed by the Board, the remaining £8000 is to be obtained by the issue of debenture stock. The first ordinary meeting of the new Company was held last week, when the Articles of Association were altered to meet the circumstances. The Gulcher lamp is a very good one, as arc lamps go; being one of the steadiest and most reliable. As with the Maxim-Weston systems, however, the Company owning this clever invention failed to make both ends meet; and technical excellence, without other indispensable elements of commercial success, was found to be of little avail. If managers and proprietors of electric lighting systems are able to learn by experience, and are not in this respect like the deservedly unfortunate Bourbons, a Company that has been blessed with a second chance of active existence ought to do fairly well by eschewing the bad old ways of its early prime, and going on in the road of unsensational, plodding endeavour. It is a common remark, with reference to mankind, that no man can expect to enjoy two forenoons in the same day. So with trading companies, one failure generally destroys their prospects of utility by sapping the confidence of their supporters, which is their life. The Gulcher Company are more fortunate than the generality of their companions born at the same period, and for the most part interred beyond the possibility of resuscitation. It is to be hoped they will do better in their second life than in their first stage of existence.

DR. NEUDORFER, of Vienna, has found in a substance called "creoline" a valuable antiseptic. It is a sort of tar obtained from bituminous coal by dry distillation. It is closely related to creosote, carbolic acid, resorcin, and hydrochinon. This substance has been found highly advantageous in preventing the spread of erysipelas, the pains of which it also reduces, and effects an early cure. By its use, the subcutaneous injections of carbolic acid are not required. He has also used creoline for the treatment of ordinary flesh wounds, and for the removal of tumours. A gauze is prepared which is dipped in a solution of creoline. The Doctor considers it to be the most trustworthy, convenient, and harmless, as well as the cheapest of the antiseptic preparations.

THE NEW READING GAS-WORKS.

REFERENCE has already been made in the JOURNAL to the opening of the new manufacturing station which Mr. Edward Baker, Assoc. M. Inst. C.E., has just constructed for the Reading Gas Company. We hope, by Mr. Baker's kindness, to be able soon to give our readers full particulars, with drawings, of these interesting works. Therefore the present notice of their completion—to the extent, at least, of being brought into use in preparation for the coming winter—must be taken as only an introductory description of the general arrangement. The fame of Mr. Baker's work has already travelled far; and many are the visitors he has had on this account, since the day last year when the members of the Southern District Association of Gas Managers went to Reading and saw the new buildings in course of erection. One could tell then what was going to be the general character of the work; and the Engineer received many well-deserved compliments upon it. Now, however, promise has been realized in achievement; and we are not exaggerating the merits of the new station in declaring it to be one of the most interesting gas-works in the United Kingdom, on account of the evidences of thoughtful design with which it abounds in every part, and of the patent thoroughness with which these designs have been carried out. Mr. Baker is a very retiring man among his fellows, and is not often heard of when controversy rages round disputed points of engineering or carbonizing practice. Those of his colleagues who do not know him, however, or know him but slightly in connection with the gas supply of the quiet town on the Thames which is mostly celebrated for biscuits and seeds, will be astonished to learn that the high-water mark of gas engineering may be seen in his works as plainly as in others of much greater pretensions in point of size. After a visit to Reading and one or two other places that might be named, one begins to perceive, if it has not been understood before, that the popular notion that interest and instruction culminate in huge works is a mistake. A great gas-works in particular may be, and often is, only a multiplication of features anything but admirable in themselves. Enormous size, of course, has its own imposing attributes; and the special interest of great works is that in them the insignificant details of small establishments are strikingly magnified—entailing developments which cannot be found elsewhere. In all essentials, however, size is often only a "blind;" and a gas-works which can only be properly traversed on a steam tramway may contain less that is worthy of study than a little place which can be walked through in a few minutes. So it is that there is scarcely a gas-works in the kingdom better worthy of a visit at this time than that of Reading; and we hope to be forgiven by Mr. Baker for saying so, and thus bringing on him more of the plague of deputations and inquiry-circulars than he already suffers from. Truth must be told, however; and having discovered what Reading has to show to interest a gas engineer, we must tell it at all hazards.

The new Reading works make a fine show from any of the railway lines approaching the town from the eastward, as they are contiguous to the South-Eastern Company's line, and are bounded by the River Kennet just before it debouches into the Thames. To find the site from the town is not, however, so easy; for it disappears as soon as one quits the vantage-ground of the railway, and is finally re-discovered at the bottom of a narrow entry round the corner of the great biscuit factory. The entrance to the works is, however, the last object of Mr. Baker's solicitude. He has nearly finished what he has to do for the present in the yard; and then at a blow a block of old buildings will be cleared away, a small linking-piece of roadway made good, and the way to the new station will be worthy of the rest of the extensions. The new works occupy a site almost adjacent to that of the old ones, but separated from it by a branch of the Kennet, over which Mr. Baker has thrown a peculiarly light and neat iron bridge for road traffic, and for carrying the new trunk mains. It is a low-lying quarter of rivers and navigation cuts; and when the Gas Company bought their new site, it lay in winter under 3 feet of water. The gasholder was the first structure put up here; and the story goes that when the Engineer took the Contractor for the tank to show him the scene of his prospective operations, they went over the whole site in a boat. It was known, however, that there was a good bottom of gravel to the half-drowned soil; and persevering dredging in the neighbouring river, and tipping the spoil on the site, have now raised it well above all risk of flooding. Heavy work with the pumps was required in order to get in the tank; and for all the other buildings the work that shows above ground is comparatively nothing to what has gone down out of sight in foundations. With a view to the future, thousands of tons of concrete have been buried by Mr. Baker on this remarkable spot; and although the present extent of the buildings does not show much for the money spent and the trouble taken, yet the foundations have been made good so far in advance of present requirements that the productive power of the station can be doubled for a comparatively trifling additional outlay. Fortunately, there is an unlimited supply of gravel in the locality, or the cost of these foundations would have been almost prohibitory.

Interest at present centres in the carbonizing portion of the works and plant; the rest being incomplete. The new retort-house, however, is in full work, supplying all the gas required for the town. It is in respect of this house and its arrangement and fittings, that the Engineer's care and thoughtfulness are most conspicuous. He had several problems to solve, as must every designer of new works; and while it is far from our desire to claim

for Mr. Baker a perfection of skill and foresight which he would be the last to appropriate for himself, it is at least possible to declare that he has brought to bear upon the problems presented to him a wealth of experience and study, and a power of originality, which command respect. Half-a-dozen engineers equally careful and skilled might have presented to the world as many different solutions of the same problems. We admit that we have not made any independent study of the case with a view to discovering wherein Mr. Baker might with advantage have done differently. All that we are concerned for is to tell as clearly as possible what Mr. Baker has actually done—leaving the credit or discredit a matter for himself and any who choose to criticize him from the standpoint of a better knowledge of the conditions and circumstances than we can pretend to; and we have been led to this from the conviction that, whether always right or wrong in the solution he has preferred, Mr. Baker has done nothing heedlessly. He has not used capital lavishly to compensate for lack of intelligence in design; but while spending money freely in order to carry out his plans in the best possible style, he has in all respects sought first that the plans should be worthy of their setting. He is fully entitled to the credit of doing his very best, like a good workman, according to his lights; and that is praise enough for any man.

The retort-house is a stage-house, to begin with. It is worthy of remark how this type of construction, which not many years ago was regarded as only permissible for the largest retort-houses in densely populated districts, where land is very precious, has of late been adopted in comparatively small works. The reason for this change is partly to be found in the success of Mr. West's stoking machinery, which has brought home to gas engineers the utility of mechanical hoisting, and the desirability of taking advantage of gravity. The wheelbarrow has been dispensed with to a very noteworthy extent since this idea has come into prominence. Mr. West's elevator has been the parent of many devices to the same end. Four settings of eight supply all the gas required in Reading—or did so at the time of our visit. These settings are heated by what we suppose we must call Klönne furnaces, but which are, in point of fact, the fruit of the experience of many men, and are as unlike the original Klönne system introduced into this country five or six years ago as can well be conceived. Whatever they may be, however, they work well and have never given any trouble. The retorts are in good heat, and ordinarily work off about 8500 cubic feet per mouthpiece per day, or perhaps a little more. A higher duty might be obtained, so far as the generators are concerned; but a glance upwards at a row of syphoned water-pipes, intended to cool the ascension-pipes by the well-known expedient, shows why Mr. Baker is not anxious to force his retorts too far. The generators stand on the coke-floor, partly projecting from the line of settings, and are quite cool, so that it is possible to touch the brickwork with the hand. They generate their own steam. There is no clinker worth mentioning, although there is good deal of breeze burnt every day. The secondary air is heated by simple regenerative channels. Altogether the firing arrangements look very satisfactory. The coke as drawn falls directly down to the coke-floor; a travelling shoot being arranged to conduct it into the trunnion waiting for it, in which it is removed to the yard. The buckstaves of the retort settings are exceptionally massive, since their duty is not merely to keep the bench together, but also to support the hydraulic mains (which are independent and separate for every setting) and the pipe connections. It is a principle with Mr. Baker that no weight whatever shall come upon the brickwork of the settings. To such a point is this idea carried, that the arches of the benches are built of specially moulded blocks, and there is a clearance left, so that even if the arches should settle, the settings would not necessarily be affected. The strong buckstaves already mentioned are connected at the top, across the top of the settings, by girders which carry the hydraulic mains and pipes. The tar and liquor are taken off separately; and every section of hydraulic main is washed out with clean water every morning. The foul main is of light steel riveted pipe, which effectually gets rid of all condensable matters before the gas arrives at the condenser proper, which will scarcely be needed before a great deal more gas than is now made is passed through the pipes.

The coal is brought to the retort-house over a viaduct from the South-Eastern Railway main line; and the trucks are run in on metals which stand over the coal-stores, on each side of the house, at a level of a few feet above that of the charging-floor. In the middle of the store is the tip, where a steam-hoist lifts one end of the truck bodily, and shoots its load down upon West's elevator working below. In this way two men—the hoisting-engine driver and his mate—can unload a 10-ton truck of coal in two minutes. In case anything should happen to the hoisting machinery, the trucks can be discharged by hand sideways upon the charging-floor, with very little more trouble. The coal storeage, which runs parallel with the charging-floor, is always kept full; and the fresh supply constantly tipped over the elevator. Fresh coal is therefore always used, except once a year, when the stock is cleared out and replenished. The drawing and charging are effected by West's hand machine; but power will probably be used when the house is in full work. It will be seen from this description that everything has been done to spare hand labour. The coal is never touched by a shovel in the ordinary way, from the time it enters the works until it is loaded up into carts as coke. The arrangements to this end will repay careful study. It is impossible to describe in general terms how it is done; we can only chronicle the fact.

The engine-house is in communication with the retort-house by means of a system of gongs, whereby signals are transmitted. All the steam required for the various engines is supplied by a pair of Galloway steel boilers, situated in a cool, lofty, and airy boiler-house. The engine and exhauster house is of plain and handsome design, and when complete will contain three of Gwynne's combined engines and exhausters of different sizes, for summer, autumn or spring, and winter use respectively. At present the two smaller sizes of machines only are fixed. There is a water tower in the same block of buildings. The purifying shed is situated directly across the yard. The condensing, washing, and scrubbing apparatus is the best of its kind, and conveniently placed. It is Mr. Baker's boast that there is not a T-piece in his works; all changes of direction of the gas being by easy bends. The same principle is carried throughout the distributing plant in the district. The pressures are remarkably uniform and steady. The other buildings completed, and wholly or partly occupied, comprise meter-house, laboratory, photometer-room, workshops, and stores. A handsome block of offices near the gate, not yet finished, completes the list of works in hand. All the buildings are faced with fine red brick, with blue brick string-courses, and are of handsome proportions and the highest style of finish. They are decidedly a credit to the Gas Company and to the town.

Notes.

THE AERATION OF WATER SUPPLIES.

Mr. Stephen E. Babcock recently read a paper before the New England Water-Works Association upon the aeration of drinking water. After quoting authorities and referring to common experience to establish the desirability of aerating drinking water to its utmost capacity, Mr. Babcock described the measures taken by himself to aerate a water supply after it had been carried for 8½ miles through a closed conduit. This conduit terminates at a point about 2500 feet from the distribution reservoir. The whole of this distance is constructed as an open paved channel, interrupted by a series of sixteen low weirs, 10 ft. long and 2 ft. high, placed along the open channel at intervals of 50 ft. and 100 ft., according to the contour of the ground. The channel is half-sunk in the ground; but measures are taken to keep out surface water. After running down this channel the water is conveyed into the distributing reservoir through a pipe, the end of which is turned up and serves as a low fountain, to give the supply a final aeration before it mingles with the waters of the reservoir. The open channel and its shallow dams can be cleaned out by draining off the whole of the water into a by-wash canal. The great point in Mr. Babcock's plan is that the water is kept in a state of constant agitation with air, from the time it strikes the first dam to the end of the aerating canal. It being as yet doubtful to what extent simple aeration may be relied upon as a means of purifying drinking water, Mr. Babcock supplemented his weirs and open channel with a coke filter, and expresses the opinion that coke makes the best filtering material generally available.

THE EFFECT OF ADDING SUGAR TO CEMENT.

Experiments upon the effect of the addition of sugar to cement mortar have been recently conducted by Captain A. von Grünzweig, of Vienna, the results of which have just been published. Mixtures were prepared of 1 cement to 3 sand with 10 per cent. of water, and also of pure cement with as much water as was required to give the mass the necessary plasticity. From 1 to 5 per cent. of dry powdered sugar was well mixed with the dry cement before gauging. The cement used was of inferior quality and only common, not selected, or "normal" sand was employed. The briquettes were otherwise prepared in accordance with the rules for testing Portland cement laid down by the Austrian Society of Engineers and Architects; but were laid aside to harden in a dry place, and not under water. For these reasons the strength procured was far below that prescribed and generally obtained. All the samples were prepared by the same person, under the same conditions, and with the same care. For every series of samples of mortar to which sugar was added, a comparative series without sugar was made. The tensile strength of the briquettes was ascertained by Kraft's cement-testing machine. It should be mentioned that the samples containing sugar (especially those without sand) showed a strong tendency to adhere to the surface of the smooth china plate on which they were placed, and also to swell. The experimenter gives full particulars of the tests, which are summarized in the *Builder*. As a general result, it is stated that with mixtures of cement and sand, hardened in a dry place, the binding effect may be increased by the addition of sugar, the addition reaching its maximum with from 3 to 4 per cent. of added sugar. With pure cement the addition of sugar had no additional binding effect.

DRY ROT IN TIMBER.

A report on dry rot in timber has been presented to the Standing Committee on Science of the Royal Institution of British Architects, by Mr. W. H. Bidlake. In this report it is stated that no wood which is liable to damp, or has at any time absorbed moisture, and is in contact with stagnant air, so that the moisture cannot evaporate, is to be considered safe from the attacks of dry rot. Woodwork painted or tarred before being thoroughly dried and seasoned, is liable to decay through imprisonment of the moisture.

Large beams should always be sawn through and reversed, so as to permit of completely drying. The ends of all timbers used in construction should be left free whenever possible, as it is mostly through the ends that moisture escapes. Stagnation of air under floors is a fruitful source of dry rot in the joists, especially if darkness and warmth are also present. The fungus of dry rot has the power of creeping over brickwork, plaster, and even glass and iron to reach woodwork at a distance. Larch appears to be better able to withstand the effects of damp than fir and pine. Wood bedded in mortar is specially liable to decay, for the water of the mortar is absorbed by the wood, and, in the process of setting, the mortar may decompose some of the organic substances of the woody fibre, especially if the lime has not been thoroughly slaked. Under favourable conditions of temperature and dryness, ill-seasoned wood may stand as well as wood that has been well seasoned; but it is far more liable to decay in a warm damp atmosphere, as it contains more fermentable substance, and affords nourishment for a far more luxuriant growth of fungus. If wood is to be creosoted, however, the sap-wood is better than the heart-wood, as it is more porous and absorbs the oil better. The report from which these observations are taken was made with special reference to 17 cases of rot in timber which were submitted to Mr. Bidlake, as a mycologist, for his opinion as to the causes and possible means of preventing this kind of decay in building timber.

Communicated Article.

MANAGEMENT OF GAS-WORKS EMPLOYEES.

SECOND ARTICLE.

In reviewing the different classes of labour that the gas-works manager is called upon to superintend, it will simplify matters to speak of each department as separate and distinct, notwithstanding the fact that in small works they are somewhat intermixed, two or more classes devolving upon one man. In works not making more than 5 million cubic feet per annum, one man alone will be able to carry on the whole during the summer months. He will do all the retort-house work, attend to the emptying and filling of the purifiers, adjust the supply pressure when necessary, and yet have time to do a little gasfitting and service laying. Passing on to works of double that capacity, we still find one man able to assist in more than one department; but as the works increase in magnitude, so does the division of labour. In very large works one man may be engaged as valvesman to see to the valves entirely, a matter that does not occupy more than a few minutes per day in small works.

In the retort-house there will be two gangs of men, each consisting of any number from one upwards, according to the number of retorts in operation. Some are regular hands, kept on from one year's end to another, whilst others are only had in for a longer or shorter period during the winter season. Every possible assistance should be offered in the way of inducing men belonging to the latter class to find summer employment in the neighbourhood—as bricklayers' labourers, harvest workers, &c.; and any of the winter hands that may happen to be out of work should, of course, have the preference in any odd jobs connected with extensions or repairs carried on during the summer. The object is to keep the odd hands together as much as possible; for several jobs may be found for them, such as painting holders and other apparatus, cleaning out scrubbers, boilers, &c. Very often there are plenty of men in the neighbourhood having summer occupations, who are only too glad to hear of regular indoor work for the winter; and it rarely happens that any difficulty arises in meeting with winter hands, but it is better to have the same ones back year after year, if possible, rather than to have a fresh lot in every autumn. In the case of the regular hands who work, "week in week out," all through the year, a week's holiday to each man in the course of the summer will usually be appreciated, and will not fail to yield good results. Some reference to Sunday labour may be expected here; but this subject can be dismissed in a very few words. It has over and over again been proved that the discontinuance of gas making on Sunday is possible, without any increase in working expenses; but that, if anything, the difference, taken all round, is rather the other way. Therefore there can be no excuse for not discontinuing the retort-house operations for at least twelve hours each Sabbath day—say from 6 a.m. to 6 p.m. Of course, in case of an emergency, an exception can be made.

The condensers, scrubbers, washers, boilers, exhausters, engines, pumps, and other machinery, will call for the services of a competent engine-fitter and assistants, who will attend to the proper working of these appliances and maintain the whole in working order. Workshops, with necessary tools, &c., must be provided; and if the works are above 80 million cubic feet per annum capacity or so, there will be a separate blacksmith's forge, carpenter's shop, paint shop, &c. Then we come to the purifying-house, where a considerable amount of manual labour, also subject to variation according to the season of the year, is carried on. The remarks about "winter hands" apply to this department also, as well as to the general yard work, such as loading coke and breeze, pumping tar, &c. There are also the subsidiary processes, such as the manufacture of sulphate or distillation of tar. If ample storage-room is available these can be discontinued during the busiest season, and thus made to assist in "levelling up" the labour sheet from week to week. A gang of men must also be kept on for the

lighting, extinguishing, and cleaning of the public lamps; also gas-fitters for fixing or removing meters, stoves, services, &c. These various matters represent the operations that are carried on as entirely separate departments in large works, but lumped together to a greater or less extent in small works.

Some of the operations above indicated offer a prospect of being replaced, partially or entirely, by mechanical power. A great deal of ingenuity has been expended upon such matters as drawing and charging retorts by machinery, automatic lamp-lighting devices, &c. The former has been developed in practice to some extent; but the latter must be regarded as still in the inventor's hands. In our present state of engineering knowledge, it may be pointed out that pumping liquids from one vessel to another, or elevating large quantities of coal, oxide, or lime, by manual labour, is a needless extravagance, at any rate where a supply of steam is available. Several simple and cheap little machines for raising liquids are now in the market; and as to the solid materials, either a hoist, or an elevator of the Jacob's ladder kind, actuated by steam or by gas power, can be used. Hydraulic power may also be successfully applied for such purposes.

In addition to the regular hands in the various departments, it occasionally happens that extra help must be called in, on account of emergency arising from one cause or another. The quality of the coal may be below par, necessitating the maintenance of an unusually large number of retorts in work. The purifiers may require changing more frequently than usual, by reason of the material used being defective or getting old, or because there is an uncommonly large quantity of impurity to be removed from the gas. A very large order for broken or screened coke may come in. A prolonged and severe frost will call for continual care in thawing the lutes on the gasholders and purifiers. Fortunately these contingencies usually arise in the winter when there are plenty of labourers to be had. Some regulations based upon local circumstances must be made with regard to the employment of these short-term labourers; they require strict supervision, and their time must be carefully checked.

The rates of wages payable are to some extent already defined by local circumstances. The price current for day labourers in any particular place will depend on the cost of provisions, house rent, &c.; and, as a rule, they are higher in populous than in comparatively thinly-peopled places. In large villages or small towns, a labourer can usually be obtained for 14s. or 15s. per week; and in towns of a population of 20,000 or so the figure of 20s. per week will not be exceeded. But in large towns 25s. or more must be paid. The greater part of the work on a gas-works can be done by ordinary labourers, who soon acquire a knowledge of the duties required; and therefore the wages offered need not greatly exceed the ordinary day rate of the district. In large works it is usual to employ men rather stronger than the average in the retort-house, in which case correspondingly higher wages must be paid.

The almost universal custom in the retort-house is to work 12-hour shifts, though in some few cases 8-hour shifts have been tried; and the men are paid so much per shift, or so much per week. The former plan is general on the large scale and the latter on the small. The purifier and yard men are usually paid at per week of six days; the hours of labour per day being those usual in the locality. In large works a great deal is done on the contract system. A captain or ganger will undertake to empty or fill the purifiers at an agreed price per purifier, or to load coke at so much per truck, finding and superintending his own labourers. The lamp lighters, having irregular hours, are sometimes men having other employment, who take their work at an agreed price. In other cases they agree to devote their whole time to the service of the gas-works, undertaking certain duties in the purifier-house or yard, or perhaps to attend at the works from four to six hours per day, and do whatever may be required, for fixed weekly wages.

Some gas engineers keep rigidly to the current rates of labour in the district and will not pay more. Others hold that it is not wise to beat down the rate of wages paid, and offer something higher, in the hope of inducing a superior class of men to offer themselves; but sometimes the same end is attained by means of bonuses dependent on results, or other additions to the wages. While it is possible, on the one hand, by paying low wages, to have the work done in a slovenly or careless manner that ensures a considerable loss to the company; on the other, it is very easy to dispose of money through the medium of the wages sheet, without getting a proper return for it. The "bonus" system, or "payment by results" has the advantage of encouraging the men to exert themselves to the utmost in order to secure the desired result; but it also carries several disadvantages, inasmuch as it opens a door for deceitful and underhanded practices. For example, suppose a bonus is offered to the retort-house men, on each 100 cubic feet per ton of coal carbonized beyond 10,000 feet. By careful attention to the heats, by getting the charges in promptly and evenly, &c., it is quite possible to secure that increased economy of coal and working which is the object desired in offering the bonus; but an apparent right to the bonus can also be made out by less honourable means, such as using heavier charges of coal than those booked, increasing the draught of the exhauster, or tampering with the water-line of the station meter. The bonus principle is not applicable to every employee on the works; and therefore, whilst it may serve as an incentive to those eligible to receive it, those who are not eligible will certainly not be stimulated, but rather the reverse. It also has the objection of cutting only one way. The men look eagerly for every penny to which they can establish a claim under the agreement; but if

on account of any neglect a result lower than the initial rate is obtained, they expect to receive the full regular rate of wages just the same. The bonus system has not answered well in the writer's experience; but this does not affect the fact that it has given satisfaction in some places, and therefore it may be introduced with advantage under some circumstances.

There can be no doubt that, especially in the retort-house, it is in the power of every man to make himself worth more to his employers than the current wages rate. Take the working of a furnace for example. The immense economy that can be obtained, in the quantity of coal necessary to secure a certain duty in the steam-engine, merely by the exercise of skill on the part of the fireman, is well known; and the same is applicable to every purpose for which fuel is used. If competition trials were instituted with retort-house furnaces, on lines resembling those which have been conducted in the case of steam-engines, some remarkable fuel results would be forthcoming. Inventors of new processes have frequently been misled by this very thing. They have put up, let us say, a new furnace; and this, worked with every possible care and attention in the way of nursing under their own personal supervision, gives much better results than those obtained in the ordinary rough-and-ready way of working. The proper way of arriving at a fair comparison, however, would be to select one of the ordinary furnaces, and repeat the experiments upon it, with all the care that has been bestowed upon the new pattern. If a gas engineer finds that he can rely upon care and skill in the retort-house, he will do well to offer increased pay for the same; but the mere raising of the wages will not necessarily secure that end. The men if left to themselves will do better so long as the novelty lasts, but will sooner or later return to their old ways.

Where men are employed in gangs or sets, it is necessary that all should receive the same rate of wages, and therefore impossible to treat every individual according to his deserts. The best way of working with the utmost economy under such circumstances is to rigidly define the work to be done by each man, and to take care, by means of strict supervision that he does it. The difficulty is increased when the work is done by two separate shifts or gangs, one taking on duty when the other leaves off. Suppose a furnace does not act properly, and there is reason to suspect neglect. In the absence of proper supervision, inquiry of the day man will probably elicit the remark that he does his best, but it is no use for him to try if others will not do the same; while the night man is positive that he leaves the furnace better than he finds it. Each man should be directly responsible to the manager or foreman for the due fulfilment of his duties; and when the responsibility is divided as in the above illustration it is better that each gang should have a foreman or head, who is intrusted with the duty of seeing that the particular work done by his gang is executed in the best possible manner.

Leaving the ordinary labourer, there will also be a need for men of a higher class, having a special technical training, such as engine men, main and service layers, &c.; or else men elected from the labourers by reason of more than average intelligence or diligence, to occupy the post of foreman stoker, foreman in the purifier-house, valve and governor house man, &c. Men of this class, having an increased share of responsibility, or being possessed of a special kind of skill, will require higher wages. When once suitable men in these capacities have been secured, it will be worth while to offer them every possible encouragement.

DEATH OF MR. J. F. BONTEMS.—We regret to record the death last Tuesday, at his residence in Canonbury, of Mr. J. F. Bontems, for many years a member of the Corporation of London, and until quite recently, Chairman of the Barnet District Gas and Water Company. Mr. Bontems had, in consequence of continued ill-health, been compelled to resign the chairmanship of the Company to Mr. J. Glaisher, F.R.S.; he taking the less exacting duties of Deputy-Chairman. This fact is announced in the report which the Directors will present to the shareholders at their half-yearly meeting next Thursday. In this position he might have been spared to the Company for some few years, had not an unfortunate accident caused his sudden removal. On Saturday, the 4th inst., the deceased gentleman attempted to enter a tram-car in the Essex Road; but before he could do so it moved on. In returning to the pavement, he was knocked down by a passing milk-van, and was rendered quite unconscious—death resulting from his injuries. At the Coroner's investigation last Thursday, a verdict of "Accidental death" was returned. Mr. Bontems was in his 75th year.

PRESENTATION TO MR. J. H. WOOD, OF SHIELDS.—On Thursday, the 2nd inst., the officials and workmen of the South Shields Gas Company met at the works to offer Mr. J. H. Wood, Superintendent, their united congratulations on the occasion of his marriage, and accompanied the expression of goodwill with a substantial present in the shape of a beautiful marble clock with bronze ornaments to correspond. Mr. J. H. Penney, the Secretary of the Company, presided. Mr. W. J. Warner, the Engineer, in making the presentation, said it was a confirmation of the opinion which they had all held, that Mr. Wood had not only won their confidence, but the goodwill of all engaged in the undertaking. Apart from his connection with the Company, he had been zealous and energetic as a member of the ambulance corps—teaching their own men while training himself. He ventured to forecast for Mr. Wood a career of usefulness, honour, and distinction. Mr. Wood, in acknowledging the gift, thanked Mr. Warner for his encouraging remarks, and the officials and workmen for their kindness in remembering him at such a period.

Technical Record.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

THE ANNUAL MEETING IN GLASGOW.

We conclude to-day the publication of the papers read at the above meeting. Next week we shall commence the general report of the proceedings, with the discussions on the papers, as passed by the Revision Committee of the Association.

SELLING GAS.

By JAS. M'GILCHRIST, of Dumbarton.

Time was, and many present (neither grey-haired or bald-headed) remember it, when coal gas, practically speaking, had a monopoly of artificial lighting. 'Tis not so now. Oil and electricity, within a dozen short years, have made wonderful advances in public favour. The former has, in some districts taken up a considerable percentage of the business that "King Gas" so long, and if I may be permitted to add, so honourably discharged. Although I admit the fact of the steady, if slow, progress of our rivals, I do not in any way wish to assume the position of alarmist. I merely wish to point out, without prejudice (as our legal friends would say), how we have lost business, through giving too little attention to the question of selling gas. Now, had we given this question a tithe of the attention that we have bestowed on its manufacture, I am convinced that our rivals would not have enjoyed one-half of their present popularity. In the past, gas companies have not considered it part of their duty to push the sale of gas—at least, in any organized or determined manner. They were monopolists, in the strictest sense of the term; and many of them, secured by Act of Parliament, assumed that nothing could interfere with the successful business they conducted, of supplying artificial light. They, therefore, did not show that vigour in pushing business usually engendered by active competition.

No doubt they were, and still are, protected against competition on the part of rival gas companies; but there are now other "Richmonds in the field." The extensive development of oil-wells in America and Russia, and the improved means of transporting oil in bulk, have led to the markets of the world being flooded with a cheap light-giving material. The effect of bringing these cheap oils into the European market has been to reduce the value of the shale oils produced in such large quantities in Scotland. In these oils we have a formidable rival, especially among the poorer classes of the community; and whilst they are gnawing our business at the one end, the electric light is canvassing for customers at the other. The latter appeals to the owners of large business establishments as well as to the wealthier classes. At the top and bottom of the ladder, therefore, influences are at work which, if not met and checked, may seriously affect the business and revenue of gas undertakings.

But there is yet another factor that we must take into account. Within recent years coal gas has been applied with great success to drive engines for manufacturing purposes. The manufacturer is now beginning to use water gas as fuel, finding it cheaper than coal gas; and several firms have erected apparatus to make water gas. In the town of Leeds, where coal gas is sold at a very low price, I see from the newspapers that one firm, formerly paying nearly £3000 a year to the Corporation for gas, has laid down plant to produce water gas; so that another class of consumers is being lost. Again, the gas cooker is challenged by the paraffin stove. Well, if the ordinary housewife is slow to adapt gas for cooking purposes—owing to the smell—she will not, I think, reconcile herself in the near future to paraffin. With all these influences at work, the life of the gas manager, like that of the policeman of the lyric stage, "is not a happy one." Although it may be sad to have to admit that we cannot look upon our rivals—oil and electricity—with a distant stare of contempt, I am not going to admit that our occupation, like Othello's, is gone. It is comforting to know that the great masses of the people prefer coal gas (amid all their growling and grumbling about it) to any other form of artificial lighting. With all its faults, the people love it still; and why not? Has it not proved itself a blessing to mankind? I say it in all seriousness, as indicating a peculiar power of coal gas, that I have known of people in company who could neither speak, sing, nor enjoy themselves until the gas was lighted. With these extraordinary qualities, I say (and I say it advisedly) we are unworthy of the positions we occupy if we cannot at least hold our own against—shall I say?—nasty cheap oil or fitful expensive electricity. I could tell a long tale about the dangers of oil and the uncertainties of electricity; but I prefer at all times to push business on the merits of our own manufacture, rather than dwell on the demerits of its rivals. We all know that coal gas, when properly applied, can "give points" to all other forms of artificial lighting, and is safer and cheaper; hence my reason for not detailing its many virtues.

In the hope of exciting an interesting discussion, I now proceed to describe my ideal gas company, hereafter known, in parliamentary phraseology, as "the company." It will, in many respects, resemble the commercial house of the present day. It will canvass for business. I may say it takes more money to sell than to manufacture a sewing-machine, that sewing-machine companies generally make large profits, and that they do nine-tenths of their business through canvassers. I think, therefore, the company will find that canvassing is worth many times the small amount that it would cost. To make the canvass successful, the company

first of all—and I would like to emphasize this point with all the strength of language I possess—must supply a gas of high illuminating power, and free from all impurities, so that a pleasant, cheerful light may be obtained. The company will find the consumers contented and happy (if that state can be acquired here) supplying a high quality of gas. Even although the charge per thousand cubic feet should be a few pence higher than is charged at present, it does not, of course, follow that the light is more expensive. In towns where the illuminating power of the gas is reduced, I believe our rivals do exceedingly well. The public want light in as concentrated a form as possible; and when a few pence per thousand cubic feet can make the illuminating power all that the consumers desire, I think it is an unwise policy to cheapen the price per thousand cubic feet at the expense of the illuminating power. The public grumble more about the quality of the light than they do about the price per thousand cubic feet. It is light, not gas, the people want; and a company should be pleased to supply the quality of light that the consumers find most beneficial. The company will also look after the internal pipes and fittings of consumers, and have them arranged according to a standard of sizes for the number of lights, &c. The company will find this a great improvement on the usual system of allowing Tom, Dick, and Harry to fix the pipes and fittings according to individual fancy. Indeed, they will find this to be absolutely necessary in the interests of consumers and shareholders alike. The company will not vex its consumers by charging that irritating and obnoxious tax, meter rents. It will, like many companies of the present day, find it much better to charge the meter rent in the selling price of gas. It is an objectionable charge in the eyes of all consumers, and ought to be abolished. This tax hinders the selling of gas. The company will possess a show-room in a convenient thoroughfare, where consumers may inspect appliances for developing the largest amount of light from the quality of gas supplied, see the latest contrivances for cooking, heating, &c., by gas, and receive instruction concerning their use. It will also hire out, on reasonable terms, every form of gas apparatus that consumers may require. This will greatly assist in selling gas. The company will also develop a field, which, as at present worked, does not add materially to the gas revenue—I refer to the sale of gas to the lower or labouring classes. It will supply gas to these classes either through the medium of the automatic meter, which is, I think, a step in the right direction, or by a system of weekly or bi-weekly collections.

With the former, when light is wanted, the lowly candle, or the bottle of paraffin, is purchased from the neighbouring shop, and often burned in a dangerously constructed lamp. The newspapers every other morning tell pitiful tales of lives sacrificed to the "Moloch of paraffin." With this meter such danger and trouble will be avoided. A penny dropped into the box will purchase a certain quantity of gas, and the best system of doing business—namely, "ready cash"—is introduced. When the great advantages of using gas become known to these classes, automatic meters will provide an easy way of selling gas in small quantities, and a means whereby a large amount of new business may be secured. Of the other system—"weekly payments"—I am glad to be able to state that it has been tried, and been found successful. Mr. Keillor, of Nairn, adopted it about a year ago; and he informs me that out of 530 consumers, 113 are paying weekly, at rates from 3d. to 1s., according to the number of lights, &c. The system resembles, and was suggested by, the Prudential Assurance Company's method of doing business—viz., by weekly payments. Mr. Keillor argued that, if weekly payments wrought well with insurance companies, they should be equally successful with gas companies; and I am glad that Mr. Keillor, after a fair trial, can recommend the system. Not only has it procured a considerable percentage of new consumers, but many who paid quarterly avail themselves of the system, which is simply on the lines of the old Scotch saying, "Short accounts mak' lang freens." This system may be compared to the "quality of mercy," because it "blessoth him that gives and him that takes." It is very easily wrought. The collector gets 5 per cent. of the money he collects; and for this remuneration he acts as canvasser, which he does alike in his own and the company's interest. I have ascertained from the manager of one of the largest insurance companies in the kingdom that it takes 16 per cent. to collect its money in small sums; but in his opinion 5 per cent. would pay very well for the collections under this system. In this and other cities I am confident that there are hundreds, if not thousands, of decent working people who cannot afford to pay quarterly accounts for gas, but who could easily manage to pay the amount of the quarter's gas if divided into weeks, and who would willingly avail themselves of this system, and be grateful to those who introduced it. Many families use oil, not because they consider it either cheaper or better than gas, but simply because they have so many uses for their limited incomes, that they cannot lay sufficient past to pay a three months' bill. Mr. Keillor may tell us to-day more of his system, which is calculated to assist materially in selling gas.

Messrs. W. and B. Cowan, of Edinburgh, have produced a gas-meter (a sample of which is on exhibition here to-day) to still further carry out the ready-cash, or rather "pay-before-delivery" system. It is a most ingenious arrangement. By it consumers can purchase from 100 to 5000 cubic feet of gas, just as they could buy as many pounds of cheese in a ready-money grocer's shop. Time will test whether the public will think fit to pay for gas before they get it; but the meter, I have no doubt, will do its duty faithfully and well. The intention is that a gas company

may be able to sell a quantity of gas to a consumer, and when such quantity has been used, the meter will stop and shut off the supply. The long moveable and stationary pointers are set by a key at the quantity sold—say, 2000 cubic feet. The moveable pointer then begins to travel back to zero, at which point it stops. By means of the stationary pointer, any dispute regarding the starting point is prevented; and, further, consumers may see at any time how much gas has been used, and the quantity still to be consumed. The meter moves the ordinary index, into which is geared the wheel of the moveable pointer; and while the latter is being actuated by a key, it un gears with the index train. The result is that the ordinary index always keeps a record, and thus checks the quantities indicated from time to time by the moveable pointer.*

The gas companies of the near future will also protest against the iniquitous system of valuation adopted by assessors when valuing gas-works. They will fight until the coal-gas industry is valued upon the same basis as other industries, and get rid of the greater part of this unjust tax that militates against selling gas. The company will also adopt the co-operative system, that has been so successful throughout the country—viz., that of making all the consumers shareholders (who are not included in the automatic or weekly-payment system), by charging deposits at, say, the following rates:—5s. for a house of one apartment, 7s. 6d. for a house of two apartments, 10s. for a house of three apartments, 15s. for a house of four apartments; larger houses at corresponding rates. The amount for shops and other places of business to cover four months' consumption in winter. From experience, I can assure you that you save much time and trouble in collecting accounts. No bad debts are made. Indeed, it is rather odd, a profit is sometimes made out of bad debts, through consumers running off and leaving deposits amounting to more than their accounts. This enables the manufacturer to sell gas at the lowest price, and when consumers get 5 per cent. on the amount of their deposits, they have "nothing in the world to grumble at." Gas companies who charge deposits as they think necessary, generally create a bad feeling among the consumers. Ratepayers, as regards deposits, should all be put on the same level. The man in good position at least should not object to pay a deposit, because by this system he does not require to pay his portion of the debts of runaway consumers in towns where deposits are not demanded.

In conclusion, the gas corporation of the future will not take gas profits to pay rates that, in justice, ought to be paid by the ratepayers generally. Public opinion is ripening on this vexed question; and the day is not far distant when this iniquitous tax will also be abolished, and gas sold at as near cost-price as possible. Mr. Chairman and gentlemen, I have done. My ideal gas company—or gas corporation if you will—is not to be found in this enterprising country. Can you give me any reason why gas undertakings should not push for business like other commercial firms?

REGENERATIVE FURNACES FOR SMALL GAS-WORKS.

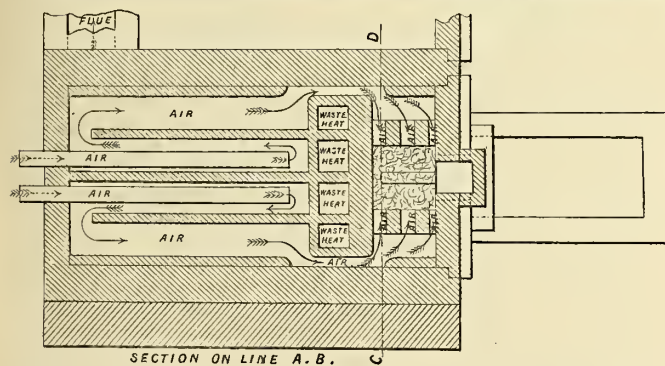

By JOHN SMITH, of Rosewell.

As most of the gentlemen here are now pretty well acquainted with the principles of the regenerative furnace, I do not intend in the following paper to say anything of a general nature with regard to it, but to confine myself principally to what I have done, how I have done it, and the results thereof.

In the month of July last, I constructed a regenerative furnace at the Rosewell Gas-Works, which is still at work, and is giving full satisfaction. The furnace in question is adapted to a setting of three retorts; and as is generally the case, the first operation was to excavate under the oven and in the floor to the depth of 3½ feet, and to underbuild the side walls of the oven. The bottom of this excavation having been laid with 3-inch pavement brick bedded in lime, the foundation of the flues and producer was commenced. The latter is placed inside the oven under the front of the retorts, and is 2 feet square inside, and 3½ feet deep. The flues—four in number, and 9 in. by 9 in. square—occupy the rest of the space, and extend 3 feet outside the back of the oven, where they are carried to the chimney by a cross flue. These flues were covered with 3-inch checked covers; and another set of flues commenced on the top of them, and covered up in the same manner. A third set of flues was built, and covered up the same way; this last covering forming the bed of the oven. The top and bottom sets of flues are for the waste heat passing from the oven to the chimney; and the middle set is for the heated air. The producer being built with these is now 3½ feet deep; a hole 15 in. by 15 in. being left at the bottom for cleaning it out. The air for the hot-air flues is admitted at the back of the regenerator, and is carried forward by two 4-inch fire-clay pipes to nearly the front end of the two centre air-flues. It goes back outside these pipes, but still in the two centre flues, and returns to the front in the two outside air-flues, entering the top of the producer by three ports at each side. The two fire-clay pipes are used for the purpose of carrying the air to the starting point; there being no other means of admitting the air to the front end of the two centre flues. The gases rising from the producer go into combustion with the heated air, and pass up the front portion of the retorts, over a middle wall, down the back portion, then enter the upper set of flues, travel forward, descend to the lower set of flues, and flow outward (as before stated) to the cross flue that leads to the chimney. The upper door of the producer

* Several references to the meter here alluded to appeared in the last volume of the JOURNAL.

consists of an iron frame 11 inches square inside, and bolted to two brick cheeks; the whole fitting into the angle formed where the front wall and floor meet. A brick to fit this door, bolted to a piece of sheet iron, serves as a cover, and can be lifted off and on when required.

The producer is filled by applying a scoop to the mouth of the retort when drawing, and is cleaned out from below every 24 hours; an excavation having been made in the floor for that purpose, which is covered over with a piece of sheet iron 6 feet long 3 feet wide, $\frac{1}{2}$ inch thick, and on the inside of which three pieces of angle iron are rivetted across to give it strength. The primary air is admitted at the door at which the producer is cleaned out. There being no fire-bars and no side holes for the admission of air, a piece of 4-inch cast-iron pipe, about 2 feet long, is laid down with one end sticking out at the door, the other reaching nearly to the back of the producer, and carrying a portion of the air to that point. This pipe also serves another useful purpose. Having no steam to keep the bottom of the producer cool, I use water for that purpose; and by allowing it to enter the pipe at something between a drop and a run, it is by the heat immediately converted into steam, and answers the purpose admirably. The distance the heated air has to travel is about 21 feet; but, the flues being large for the small quantity of air required, it travels very slowly, and before reaching the producer is nearly as hot as the inside of the oven. The size of the flues for the waste heat—four in number and each 9 in. by 9 in. square—may seem to be large for the size of the oven; and I have no doubt they would do if they were smaller. This, however, was the size which was most convenient for me, and I thought it best to err on the safe side; for if at any point the flues are contracted, intense heat, choking up, and destruction to the brickwork is generally the result. In the construction of this furnace, I have taken a slight departure from any I have seen or heard of—that is, in making the horizontal part of the building the conducting partition, or the partition between the waste heat and the heated air. My reasons for doing so are these: The vertical portion of the building has to be of some strength, because it is upon this that the whole structure rests; and, there being no stress upon the horizontal part, it can be made an inch or two thinner, and therefore there is much less of that good non-conductor—brick—between the two. The horizontal part, which consists of covers, also makes the isolation between the flues more

complete. Another departure from the usual method is in filling the whole space under the oven with flues, and not leaving a vacant space as is usually done. When the producer is placed inside a small oven, it and the side walls occupy nearly 4 feet. The space, therefore, left for the flues is very limited. In this furnace I have dispensed with flues at the side of the producer, but have used up all the rest of the space for that purpose.

This furnace was lighted up in August last; and is still in operation, giving general satisfaction. Some things about it seem to me rather strange. For instance, I have read about it being possible to regulate the secondary air supply by looking into the oven and judging by the appearance of the flame. I had pictured to myself the gas rising black from the fuel, and going into flame—Bunsen burner like—when it met the hot air. In this I was disappointed. It is true that when the charge is newly drawn, there is some flame, and you can see the combustion taking place at the air ports; but, generally speaking, there is no flame at all to be seen. Still the heat kept increasing, until it had to be checked by the damper. What then could be keeping up the heat? It could not be the hot air passing through the fuel, as in the old fireplace; for the air is admitted on the top of the fuel. I have no doubt most of the gentlemen here know what was puzzling me; and what I afterwards found out for myself—viz., that the blue flame of a Bunsen burner, when placed inside a fire or red-hot oven, entirely disappears; and although still there, does its work invisibly. As far, then, as my experience goes, you cannot well regulate the quantity of air by sight, but must judge by results; and in my case the best results were obtained by an opening of 2 square inches in each of the pipes at the back of the regenerator.

At first I cleaned out all the ashes in the producer every morning. By doing this, a good deal of heat was lost, as it took the fire about two hours before it was at its full strength again. Latterly, I found it better to clean out only what was lying black at the bottom; there being generally a quantity of red clinkers sticking upon the sides, and often bridges right across near the top. A few strokes from the steel bar from above sent the whole to the bottom, and formed a much better foundation for the fresh fuel than the clean bottom of the producer. If fire-bars are used, this might be different. The clinkers are sometimes rather hard to remove if the water is neglected, when the heat is very high. A small quantity of spent shale, however, drawn from the retorts along with the coke, was found to be an excellent thing for preventing clinkers being formed. The fire is damped down at night for about seven hours, during which time there is some loss of heat, but nothing like what would be with the old fires. At the point where the waste heat first enters the flues, there is an accumulation of dust 3 inches deep; otherwise the flues are as clean as at the commencement. I attribute this deposit to the fact that I use dross to some extent for firing. The brickwork does not appear to be affected in the slightest; although the heat was sometimes so intense that I was afraid to look into it, and as far as I can judge from it at present would last for a number of years.

And now, as to the important question of economy. Would the saving effected compensate for the first outlay? In my case the saving is very great; but there are special circumstances to take into account. In the first place, the gas-works under my charge are close to the Whitehall Fire-Clay Works, where the best of material can be had at a moderate rate—the cost of carriage being almost *nil*. The whole cost of this furnace amounted to only £8. In the next place, I use shale to a large extent for making gas, from which there is no coke; and I have therefore to use a large quantity of dross. Formerly I required to have two ovens going for five months of the year; whereas, with the improved heat working off the charge in three hours when it used to take four hours, I can now do with one oven going. The result of the whole is that, whereas formerly I used 18 tons of dross per month, I now only use 3 tons; the coke from one of the retorts, which is charged with splint, being nearly sufficient to keep up the heat. But, as I said before, this is partly due to special circumstances; and the saving is not so much in the summer time. There is also some saving of labour, as the fire requires less attention.

In this furnace, although I had what appeared to me to be feasible reasons for departing from the usual mode of construction, I do not claim to have constructed a better furnace than anyone else. It does its work well, and gives no trouble whatever; but that may only go to show how the same end may be accomplished in many different ways. Had I been less favourably situated, I might not have been justified in going the length I have done. More especially was I convinced of this when seeing Mr. Turnbull's furnace at Lauder in April last. It does its work beautifully; is simplicity in itself; and would not cost half of what mine would.

The question therefore seems to be, What length should we go to whether should we attempt to recover the whole of the waste heat, or be contented with taking the best of it? I think I have gone quite far enough; and in another furnace which I am at present constructing I have not gone so far; but having a large choice of materials ready at hand, and full liberty from my employer to use my own discretion in the matter, I was placed in a more favourable position for trying the experiment than most of those in charge of small gas-works.

In the furnace which I am at present building, the producer is exactly the same as in the first one, but the flues are different. The waste-heat flues are three in number. The two outside ones are 18 inches deep and 9 inches wide, and the middle one is 18 inches deep and 12 inches wide. The heat after passing over the retorts descends at the back of the oven into the two outside flues, comes forward to

the back of the producer, and returns to the chimney in the centre flue. Each of the two partitions between the centre and outside flues consists of two 3-inch brick walls 6 inches apart, and tied together with baffle bricks forming something like a hollow brick wall. These hollows are used as hot-air flues. The air is admitted at the front, and passes along the side of the producer and along the bottom of the two outside flues in a 5-inch fire-clay pipe. When at the back end of these flues, it is turned into the hollow walls, travels forward, and ascends into the bed of the oven, where it is conducted into each side of the producer by a channel 6 inches broad and 3 inches deep. The result of my year's experience has led me to modify the system thus far. I do not expect any better results from this than from my first one, but it is much less complicated, and will cost only about one-half. Such a furnace as this would be of considerable advantage in any small gas-works, more even than in a medium-sized works where a regular night shift is kept on.

THE SCRUBBING, CONDENSING, AND WASHING OF COAL GAS.

By WILLIAM KEY, of Tradeston, Glasgow.

In considering these subjects, I shall do so in the order given in the title to this paper, though not for any fanciful or accidental reason; for as I proceed it will become apparent to you why they are so placed. I shall also deal with the arrangement from a consideration of the mechanical effects produced on the gas, and will not enter into any question in the meantime of any improved results or otherwise in the secondary products either by tar or ammoniacal liquor, from the fact that there has been no opportunity of forming an opinion thereon.

Scrubbing.—The scrubbing and washing of coal gas have of late years become almost synonymous terms; for in both vessels water is the chief agent employed, and motive power is also brought into requisition for both sets of apparatus, not only to rotate the apparatus, but also to supply means to distribute the water, and work up the resultant ammoniacal liquor, by repumping, &c., to the desired strength of the contained ammonia. I shall, however, make a thorough distinction between these apparatus by designating the scrubber an apparatus for the extraction of the heavy condensable vapours; and no water will be used in connection with the arrangement I am about to describe for the purpose. Fig. 1 is designed for the extraction of the tarry and watery vapours from the gas, while it is still hot. The gas flows direct to the scrubber on its leaving the hydraulic main. The passing of crude gas in pipes, along with the tar that may be condensed from it in its travel, for considerable distances is most objectionable, and should be carefully avoided. The temperature of the gas must not be allowed to fall under 120° Fahr., and is preferably conducted to the scrubber as hot as possible.

This scrubber is designed of a capacity to thoroughly deal with 60,000 cubic feet of gas per hour; and is 5 ft. 3 in. inside diameter, by about 21 feet in height over all. The gas travels upwards for 15 feet of this height, which is the distance between the inlet and the outlet pipes. Similar vessels may be placed in a horizontal position, and the one over the other, to effect the same purpose. The outer case of the scrubber is of wrought iron, and is lined the entire length with corrugated sheet iron. A shaft passes through stuffing-boxes in the bottom and crown, to which is attached a grooved pulley, to be driven by a rope from another of a larger diameter fixed on a main shaft, and driven by an engine; so that by frictional, or other gearing, one or more of the scrubbers may be set in motion as the increased manufacture of gas may demand. Keyed on to the scrubber shaft are several cast-iron arms, to which are attached fans, butterfly-wings, or "wipers," made of corrugated or ribbed sheet iron as shown; or several layers of wire cloth of various meshes may be used. These are caused to rotate at a speed of about 300 revolutions per minute; whereby the gas is repeatedly forced to pass through the narrowed and irregular passage between the corrugated iron lining of the outer case and the ribbed wipers. Thereby the gas is impinged upon by the revolving surfaces; and otherwise is made to impinge upon the corrugations of the scrubber case. Thus the whole of the tarry and watery vapours are extracted. In a vessel of this size, the flow of gas, at the rate of 60,000 cubic feet per hour, is sufficient to refill it three times in a minute; so that the wipers, revolving at 300 revolutions per minute, enables the gas in its passage through the vessel to receive 100 wipers or switches from the wipers before it passes off at the outlet completely scrubbed and clarified. I have here a model of this scrubber, made somewhat after the design shown by fig. 4. The internal diameter between the corrugations of the case is 5 inches; and the height of the travel of the gas is 14 inches between the inlet and outlet.

I passed about 50 cubic feet per hour of crude gas through the scrubber, at a temperature of 120° Fahr., while it was stationary. These papers I now show you were exposed at a distance of (say) 0·1 inch from the outlet for 15 seconds by a stop watch; and they received the impression shown, from the tar in the crude gas impinging on the surfaces. Thereafter the model was set in motion; and the other side of the papers were exposed for a similar time, with a result as shown. The whole of the tarry and watery vapours had been eliminated; and the surface of the paper impinged upon remained quite clean. Having attached a meter to the outlet, both while the scrubber was stationary and in motion, it was found that there was no retarding effect to the flow of the gas during the latter as compared with the former experiments. The same volume of gas was registered each time; thus indicating

that the apparatus caused no back pressure—in fact, the water-line of the pressure-gauge remained steady under both conditions. The crude gas by this new process, having been thoroughly scrubbed and clarified, is now in a proper condition to be passed on to the coolers, generally termed the condensers.

Condensing.—Of all the apparatus used in the purification of coal gas, the designs for condensers are of the most heterogeneous description; and in some gas-works, as more surface was required for this purpose, a different form has been brought into use each time, so that sometimes the gas is partly condensed by passing through the various sections in a combination with several of the following types of condensers:—An enlarged hydraulic main; a pipe fixed round the inside of the retort-house; a pipe carried round the outside of the retort-house; an old boiler; a rectangular cast-iron box; a disused gasholder; a gasholder tank; pipe condensers by far too small; pipe condensers by far too large; horizontal pipe condensers; vertical pipe condensers; spiral pipe condensers; portions of annular condensers; portions of battery condensers, &c. It is impossible to discover the particular recommendation that accompanied each section, and decided the position of each design along the line of cooling operations.

For many years past I have experienced much difficulty in speaking in the presence of gas manufacturers of the temperature to be maintained in the cooling process; in fact, I have been frequently assured that the temperature has not in any way to be considered in the purification of coal gas, and if the condensers possessed the quality of being able to lower the temperature of the gas to that of the atmosphere, then they were considered to be efficient in every respect. Bearing on this subject, I will read to you the letter which appeared in the "Correspondence" columns in the issue of the JOURNAL OF GAS LIGHTING, dated Oct. 4, 1881.

Of all condensers, I consider that the form most destructive to the gas in its application is the pipe condenser carried in long straight lines, of a spiral form, with the pipes laid to a slight continuous fall, so that the gas might travel in contact with the tar. Then perhaps the vertical pipe condenser is the next most destructive; and along with this form, I would class the annular condenser—condensers so formed that when the temperature has fallen under 100° Fahr., the gas is passed slowly through a vessel of considerable area, and then through a small pipe, with consequently a very much increased velocity, to again enter a large vessel or chamber. This process, when repeated several times, must be very destructive to the illuminating power of the gas, and especially so as the temperature lowers, owing to the scrubbing process in these small pipes by the contact of the gas and the velocity of the impact with the cold and tarry surfaces—similar to what is frequently observable in towns where a rich gas is manufactured. The main-pipe, which is too small to permit of the district being supplied under a low pressure, and a slow delivery, has to be put under a higher pressure. The gas passing through it at a great velocity, hydrocarbon vapours are deposited; and the rich gas, by frictional contact with such a surface at a low temperature, is deprived of its light-giving hydrocarbon vapours, and is found to be of a much lower illuminating power further on than when it was sent from the gasholders.

The gas as it passes from the hydraulic main does so in the familiar condition of being accompanied, while it is still hot, by a dense brown vapour, resembling smoke; the visible matter being hydrocarbon—tarry and aqueous vapours held in suspense. Any form of condenser to which the gas in this state is led which necessitates it flowing through long straight lengths of pipe at considerable velocity, only serves as a means of carrying forward as far through the apparatus as possible these tarry vapours, because of the quick travel along unbroken lengths of pipe, and owing to the affinity tarry matter has at low temperature for the hydrocarbon vapours in the gas, the gas is lowered in illuminating value by several candles in passing through the last portion of such condensers where the temperature is low.

Some of the reasons why the annular form of condenser is one of the worst to employ as a cooler of coal gas are: (1) Because, the gas passing up or down the narrow annular space with a considerable velocity in a straight line, the tarry vapours are carried forward uninterruptedly. (2) The air space, being surrounded by the annular chamber containing hot gas, the air in its passage upwards becomes heated, so that the upper portions of the condenser tubes thereby lose much of their cooling power. (3) Owing to each individual annular tube being entirely separated from its neighbour, the changes of temperature brought about by hot rays of the sun, sudden showers of rain, by heat by day, and by cold by night. (4) Their singular form preventing thorough control over the temperature of the gas in severe frosty weather.

I have not prepared a diagram to show you what, in my opinion, is the only true principle on which to construct what would be an effective condenser; but I may be privileged on another occasion to deal with the design of condensers. Meanwhile, it is enough if I say that apparatus for the cooling of coal gas, to be effective, must, in the hands of the manager of the works, be under perfect control; and not like the annular condensers, allow the temperature of the gas to be so influenced by a sudden outburst of sunshine as to cause the thermometer to register an increase of 30° Fahr., or during a day of rain a lowered temperature by 20° or 30° Fahr. The apparatus should be so constructed, that one-fourth, one-half, or three-fourths of it may be thrown out of action at will. Some to whom I have spoken have objected to this because of the first cost, and no amount of argument could persuade them that a careful study and watchfulness over the temperatures would enable them to save

their first-class coals, and to work with a cheaper variety, and thereby the whole first cost of a proper condenser would be saved in one winter. Each section of condenser should have a series of thermometers and moveable discs encased in glass, to show at a glance the temperatures and position of the controlling appliances, which, in the hands of the manager, would be adjustable week by week, day by day, or even from hour to hour if necessary; and by the application of a system of levers to control the whole without in any way altering valves or gas passages, unless when a change of surface, by putting in or out of action a section of the condenser, is required. An apparatus of this kind must not have the error of all vertical apparatus now in use—that of the air which comes in contact with the lower portions becoming heated and ascending, and getting more heated as it rises in contact with the pipes or surfaces—extracting less and less heat from the apparatus as it reaches the top; so that in our very variable climate, in all weathers, sunny, showery, frosty, or mild, and in all conditions of the manufacture, be it large or small, the condensing apparatus should be adjustable to all variations, and in the hands of the engineer be controllable to a steady outlet temperature of 60° Fahr.

In works where the gas is still maintained at an illuminating power of anything above 20 candles, the adoption of the scrubbing process just described, and so clarifying the gas before it enters the condensers, will enable the gas to be manufactured much more cheaply; and the greatest benefit will be obtained by those who fix upon a standard of higher illuminating power. In such works, by the employment of the old method of condensation, the most serious depreciation in the quality of the gas would be experienced. The hydrocarbon and other vapours that it is desirable should be taken from the gas as soon as possible after leaving the retort having been extracted by these scrubbers, the condensers will now properly perform their functions, in simply cooling the gas from 160° or 120° down to 60°; and they will remain one of the cleanest portions of the apparatus in a gas-works. The exhausters will also be freed of gritty and tarry matter. By passing the gas too hot into the washers, the ammonia to be extracted is apt to remain in the gaseous state; and when the liquor gets heated above 70°, it loses much of the power of absorption from the loss of affinity which water has for the ammonia at lower temperatures. The temperature of the gas is reduced in the condensers to 60° in order to better prepare it for being passed on to the washers.

Washing.—The washer is an apparatus wherein water is employed to wash the gas. The water may be quiescent, and the gas caused to bubble up through it; or the water may be pumped up, or by other motive power made to drip through the gas as it passes through the vessel; or wetted surfaces may be rotated and exposed to the passage of the gas—all with the object of eliminating the ammonia and other impurities. Many managers have experienced in both mild and severe winter weather, a state of things whereby the washers act as condensers; and the liquor in the tanks rapidly becomes coated to a considerable depth with naphtha. The apparatus I am about to describe—in conjunction with the scrubber and condenser arrangements just mentioned—is designed so that the temperature of the gas would be prevented from being unduly cooled, and also the passage of any tarry naphtha to the washers would be an impossibility. The liquor would be made to do a maximum amount of duty; and the quality of the gas will not be impaired in passing through the water.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

I have here an apparatus to illustrate the effect produced on illuminating gas by its coming into contact with oil, and before proceeding further will show it in action. The vessel is about 2½ inches in diameter and about 1 foot high, filled with small pebbles. I will now light two jets of equal size and brilliancy. The gas to supply one of them passes up through this small apparatus; and the gas to supply the other is branched off from the supply-pipe to it. Having now poured in the U-pipe by the filler a small portion of this crude heavy dead oil, obtained from the Clippens Oil Company's works, you will be enabled to at once observe how the flame of gas at the jet on the small scrubber has almost entirely lost its luminosity, although the shape and size of the flame remains as large as before. The gas having transferred its richest light-giving hydrocarbon vapours to the oil, of course the oil is increased in volume to the extent of the vapour extracted from the gas. This same thing takes place in the washers, and with the present form of condensers, especially in frosty weather; and the loss of the light-giving properties of the gas requires to be made up by an increase in the quantity of high-class coals used, which will often, in a single month in midwinter, represent a sum equal to the value of the whole plant employed in washing the gas. The gas, in passing through the washers and scrubbers as at present constructed, is exposed to an enormous condensing surface, and the temperature of the gas, which had left the condensers at 60°, will now be found at 40° or even lower than 35° Fahr. In

frosty weather, the contact of gas rich in hydrocarbon vapours with the oily and tarry surfaces of the scrubbing liquor as it passes through the vessels at this low temperature tends to, and does cause the quantity of tarry naphtha in the vessels to increase, with the result that the illuminating power of the gas is reduced in the same ratio.

Everyone is familiar with the beautiful display of prismatic colours resulting from the letting one drop of tar fall on to the surface of water; and you have doubtless frequently wondered at the enormous surface one drop will cover. This film of oily tar on the surface of the water is very thin; yet the water under it has received a coating which prevents contact by air or gas. If the liquid so coated be ammoniacal liquor, such a film would prevent the escape of ammonia. If coal gas therefore be admitted to the washers in an imperfectly cooled, or in an unclarified condition, the drops of water dripping through the vessel, or the wetted surfaces which the gas meets with in its course, are instantly coated with a film similarly to the water just mentioned; and the efficacy of the ammoniacal liquor for further extracting ammonia and sulphur compounds from the gas is impaired. Hence perhaps the most valuable result from the adoption of my suggested system of scrubbing and condensing will be found in the increased efficiency of the washers.

Everyone knows that if a drop of water is broken up into numberless fine particles, such as mist or spray, thousands of times more surface is exposed on such a condition as compared with the surface of the drop. From this it is plain that, to get the greatest amount of work from water, instead of allowing it to pass through the gas in drops or small streams, each drop in falling only making an imaginary line through the gas (just as you would draw a vertical line on paper with a ruler), these should be dashed into spray, so that the largest possible surface be exposed to the gas.

I have designed a washer which will not only prevent the excessive cooling of the gas, but will by its powerful application in a comparatively small space, permit of the rapid passage of the gas and the maintenance of the temperature at the outlet as near 60° as possible; and the gas will flow through the liquor that is lashed into foam or fine spray. The apparatus is shown in vertical section and cross section in fig. 3. This washer itself is very similar in design to the scrubber, but has fixed to the crown, on its underside, an annular water-tank and air vessel, to which are attached ten tubes, radiating from the tank and passed through the sides of the cover to afford access for cleaning the numerous small holes in them and in the bottom of the tank. Through these holes the water falls on to the revolving corrugated iron fans or wipers. By these the water is at once lashed into fine foam or spray, and with the gas is whirled round the corrugations of the lining of the case; and the gas will be struck by the wetted surfaces of the corrugations of the fans or wipers about 200 times ere it reaches the outlet—the centrifugal action causing the gas and spray to rapidly whirl through the wiper corrugated passages outwards. I have arranged a series of bevelled trays, whereby the gas from a lower chamber in passing upwards into the next higher one has to pass through a 20-inch opening in the centre; and the water in falling from a higher chamber to a lower is directed by the bevelled plates to the same opening. These plates have a large number of small holes, through which a portion of the water will drip on to the revolving wipers.

From the foregoing, the following claims have been brought before you as the object of my paper:—(1) That the crude gas should be led while as hot as possible, direct from the retorts to the scrubbers. (2) That a scrubber, somewhat after the design I have submitted to you, should be employed to scrub the gas perfectly clean from the tarry hydrocarbon and other vapours which it is desirable should be eliminated from the gas before it enters the condenser. (3) That the condensers should be employed solely as coolers, and not used as tar extractors. (4) The gas having first been clarified by the scrubbers, the condensers will remain clean if so used. (5) That the condensers, to be efficient in the hands of the engineer at the works, must be adjustable to alterations in the manufacture and variations of temperature; so that a steady outlet temperature of 60° Fahr. be maintained. (6) That, by these arrangements, the gas will be of higher illuminating power by its passage through the condensers in a clean state, in place of the tarry condition as at present; especially so will this be the case where the gas in the condensers has been allowed to fall to a temperature approaching that of the atmosphere in severe winter weather. (7) That by the scrubbing process and clean cooling of the gas, the washers will receive the gas in a condition to enable them to do a maximum duty. (8) The ammoniacal liquor will remain clean; and the liquor will be the more easily worked up to the desired strength. (9) The quality of the gas will not be destroyed as at present by contact with the oily and tarry surfaces of the liquor in the washers in winter.

A NEW and ingenious scheme for sinking a shaft through sand, silt, and wet sloshy grounds, and excavating it like rock, has just been successfully tried in Belgium. Large iron tubes are sunk in the sand or mud about 3 feet apart, and in these tubes smaller ones are inserted, through which circulates a cool solution of magnesium chloride. The sand is frozen for a distance of 3 feet around the tubes. It resembles rock, is hard and compact, and can be excavated in the same manner as rock. It is possible that the process can also be used to advantage in the digging of foundations where water and sand are sources of trouble.

IMPROVED APPARATUS FOR TESTING AND ANALYZING GASEOUS MIXTURES.

In the third number of the *Zeitschrift für Analytische Chemie* for the current year various improvements in apparatus for the analysis of gases are noticed. A brief description of some of them may be of interest to our readers.

An apparatus designed by Herr F. Fischer consists mainly of three upright tubes—(1) a long laboratory-tube, in which absorptions and explosions are conducted; (2) a measuring-tube or eudiometer, surrounded by a water-jacket to ensure uniformity of temperature; (3) a pressure-tube connected in the usual manner with the eudiometer. The absorbent liquids and water for cleansing purposes are admitted to the laboratory-tube from a receptacle at the top, by means of a stopcock; whilst the transference of gas from the laboratory-tube to the measuring-tube and *vice versa* is effected by raising or lowering mercury reservoirs connected to the bottom of each tube respectively, and shut off when necessary by clips. There are two stopcocks between the laboratory and measuring tubes. The one nearest the latter tube is a simple stopcock, and serves to shut off the measuring-tube; whilst the other is a three-way cock, and permits of connection being made with the external air. It serves for the introduction of the gas for analysis in the first instance, and subsequently to admit gaseous reagents, as well as for the egress of wash-water, &c. In apparatus of a somewhat similar character, Mr. Alfred H. Allen uses a Lunge's nitrometer for the measuring-tube; whilst Mr. Sinibaldi places the measuring-tube in the pressure-tube, and Mr. J. B. Mackintosh, in a modification of Elliot's apparatus, has amongst other conveniences an arrangement by which the gas under examination can be shut up in the measuring-tube during the introduction of oxygen or air for explosion, and hence avoids any possibility of loss.*

Many modifications of Bunte's and of Orsat's apparatus are proposed; but the simple arrangements, devised by Herr Franke, shown in the annexed diagram, is suggested to replace them for technical purposes, and more especially for the analysis of chimney gases. It consists of a glass tube of a capacity of exactly 100 cubic centimeters (including the wide bore of the middle stop-cock), enlarged at the upper end A, and graduated on the narrower part. The upper end terminates in quite a small tube and stop-cock, while the lower end is connected by means of a wide-bore stop-cock with a glass chamber B, which is intended for the introduction of reagents, &c., and can be closed air-tight at will by means of a hollow glass stopper, fitted with a tube and stop-cock. When in use, the apparatus is best filled by allowing the gas for examination to stream through it. If, however, only a limited quantity of gas is available, the apparatus is filled with water, the stopper fixed in, and the upper narrow tube connected with the source of gas. All the stopcocks are then opened; and when the water has run out to about half way down the reagent chamber, the upper stopcock is closed, and the whole apparatus transferred to a stand, and supported in a vessel of water, where it is adjusted so that the levels of the water both inside and out are at the same height. The wide-bore stopcock is then closed. The apparatus now contains a definite volume of gas under the prevailing atmospheric temperature and pressure; and it can be treated and agitated with various reagents in the following manner:—

Remove the stopper, and fill the chamber with the reagent; replace the stopper, open the wide bore stopcock, allow the reagent to flow into the tube, and close the stopcock before all the liquid has flowed in; then agitate well, and finally let the reagent flow into the chamber again; wash out the reagent chamber, and measure by adjusting the levels of the internal and external water and reading the graduations.

Herr E. H. Keiser has introduced an apparatus in which the weight of mercury displaced by the gas is ascertained, instead of measuring the volume of the gas in the ordinary way. Herr A. Elhrenberg has constructed an apparatus for rendering the analysis of gases by combustion more accurate.

The following simple appliance is recommended by Herr W. Thörner for the collection and direct analysis of the gases dissolved in water. A flask full of the water to be examined is connected with a measuring cylinder filled with water which has just been boiled and is still warm. The pressure in the cylinder can be increased or reduced by raising or lowering a reservoir connected with it, containing some of the same warm water. The reservoir is lowered, and the flask of water raised to boiling point. The gas collects in the upper part of the measuring cylinder; and, to prevent its being absorbed by the water, oil is run in through a funnel at the top so as to form a protective layer. The gas is readily measured, and, by means of a three-way cock at the top, beneath the funnel, may be easily transferred to any other apparatus for further examination.

When estimating carbonic oxide, it is well to remember that ethylene is also absorbed by cuprous chloride; ethylene must therefore be removed—*e.g.*, by means of fuming sulphuric acid—before proceeding to dissolve out the carbonic oxide. It is also desirable to use fresh cuprous chloride for each determination.

* An illustrated description of this apparatus appeared in the *JOURNAL* for Dec. 20, 1887 (p. 1036).

GAS COKE FOR STEAM-BOILERS.

SIR,—I have read with pleasure the article on this question in your issue of the 24th ult., and agree with you that coke is not sufficiently appreciated by the gas world or the general public for use as house fuel or for steam-boilers.

I have lately visited some gas-works where, having no market for their good dust coke, they have to pay a small sum per load to get rid of it, to be thrown away as dirt. At other works, however, they are so alive to its value (or there is a better market), that their coke is broken into four or five sizes, varying from dust up to pieces say about 1½ inches in diameter. Generally this careful division is not made, although it deserves more attention. The dust or *unsaleable* portion should, if possible, be burnt at the works, either for the retorts or the steam-boilers. The smallest breeze can be burnt for producing steam, and nearly always alone. In some few cases it pays to mix it with from 10 to 15 per cent. of coal dust, depending upon the local prices. The smallest breeze cannot, of course, be used for domestic purposes, nor burnt in the usual way; but it can be easily utilized by a forced draught, and it then becomes all profit to a gas company instead of a loss.

For economy in the evaporation of water into steam, it is important that the feed water should be measured into the boilers; and this can be done as easily as gas. Weekly accounts should be kept of the weight of fuel burnt, ashes, and amounts of incombustibles, &c., and such returns reasoned upon. I am glad to see that this standard of comparison is coming more and more into general use for determining the cost of fuel for evaporating 1000 gallons of water from a certain temperature. Dust coke also is being more and more burnt. When tar is used for fuel, a comparison can be easily made between the cost per 1000 gallons of water evaporated and that of coke. In gas-works, owing to the fact that cash is not paid for the ordinary coke made and burnt by themselves, the amount used is frequently disregarded, and no accounts kept. The companies should, of course, burn the least saleable portion of their coke heaps.

Bermondsey, S.E., Aug. 11, 1888.

B. DONKIN, jun.

P.S.—The results of some interesting experiments made by the great French authority M. Scheurer-Kestner with an elephant boiler and Welsh coal have lately been published in a recent number of the *Bulletin de la Société Mulhouse*.

LAYING MAINS OVER RAILWAY BRIDGES.

SIR,—A water company for whom I am acting, are at present laying a 9-inch main through a public road which is intersected by two single-span masonry railway arches belonging to different companies. One of the companies has given notice that before laying the main over their bridge, they require the water company to make application to them for their consent, and to enter into an agreement with them.

The water company is a statutory undertaking, incorporated before the railway was made; and they have the Water-Works Clauses Acts of 1847 and 1863 incorporated with their Acts. The road is a public one, and within the area of the water company's limit of supply; and the company had a main laid in the road prior to the construction of the railway.

I consider that, the road being public, the water company have the power to lay the main without the consent of the railway company, and that the latter have no ownership in the soil between the crown of the arch and the surface of the road (See 10 and 11 Vict., cap. 17, sec. 28). I have previously laid mains over railway arches without such a point being raised. Section 19 of the Railway Clauses Consolidation Act 1845 (8 Vict., cap. 20) would appear to bear somewhat on the point; but it is not as definite as could be desired.

If railway companies have the power which is claimed in this instance, it would be at the option of a railway company to prevent gas and water companies from fulfilling the obligations imposed on them by Parliament.

I am desirous of knowing if any of your correspondents have had such a question raised before; and, if so, how it has been dealt with.

Aug. 8, 1888.

WATER-WORKS MANAGER.

* * It may be of interest to give the section referred to by our correspondent, as well as the preceding one—both bearing, to a certain extent, upon the point raised by him:—"XVIII. It shall be lawful for the company, for the purpose of constructing the railway, to raise, sink, or otherwise alter the position of any of the water-courses, water-pipes, or gas-pipes belonging to any of the houses adjoining or near to the railway, and also the mains and other pipes laid down by any company or society who may furnish the inhabitants of such houses or places with water or gas, and also to remove all other obstructions to such construction, so as the same respectively be done with as little detriment and inconvenience to such company, society, or inhabitants as the circumstances will admit, and be done under the superintendence of the company to which such water-pipes or gas-pipes belong, and of the several commissioners or trustees, or persons having control of the pavements, sewers, roads, streets, highways, lanes, and other public passages and places within the parish or district where such mains, pipes, or obstructions shall be situate, or of their surveyor, if they or he think fit to attend, after receiving not less than 48 hours' notice for that purpose.—XIX. Provided always, that it shall not be lawful for the company to remove or displace any of the mains or pipes (other than private service-pipes), syphons, plugs, or other works belonging to any such company or society, or to do anything to impede the passage of water or gas into or through such mains or pipes, until good and sufficient mains and pipes, syphons, plugs, and all other works necessary or proper for continuing the supply of water or gas as sufficiently as the same was supplied by the mains or pipes proposed to be removed or displaced, shall, at the expense of the company, have been first made and laid down in lieu thereof, and be ready for use in a position as little varying from that of the pipes or mains proposed to be removed or displaced as may be consistent with the construction of the railway, and to the satisfaction of the surveyor or engineer of such water or gas company or society, or, in case of disagreement between such surveyor or engineer and the company, as a justice shall direct."

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, AUG. 6.

The Municipal Corporations (Local Bills), Ireland, Bill was brought up from the Commons, and read the first time.

TUESDAY, AUG. 7.

The following Bills received the Royal Assent by Commission:—Bristol Water Bill, Hexham Local Board Bill, Lancaster Corporation Bill, Llanelly Local Board Bill, Nelson Local Board Bill, Staffordshire Potteries Water Bill.

FRIDAY, AUG. 10.

The Municipal Corporations (Local Bills), Ireland, Bill was read a second time.

HOUSE OF COMMONS.

TUESDAY, AUG. 7.

METROPOLIS WATER ACTS CONSOLIDATION.

Mr. F. SEAGER HUNT (Marylebone) gave notice that on an early day he will move for leave to bring in a Bill to consolidate the Acts relating to the Water Supply of London.

THURSDAY, AUG. 9.

RETURNS AS TO GAS UNDERTAKINGS.

The usual returns relating to all authorized gas undertakings in the United Kingdom (made up in the case of companies to Dec. 31, 1887, and in that of local authorities to March 25, 1888) were presented.

SATURDAY, AUG. 11.

WATER SUPPLY STATISTICS.

A return was presented, giving the particulars in regard to water supply for which Mr. J. F. B. Firth moved on the 7th of June last (see JOURNAL for June 5, p. 1007).

Legal Intelligence.

HOUSE OF LORDS.—FRIDAY, AUG. 10.

(Before the LORD CHANCELLOR, LORD WATSON, LORD FITZGERALD, LORD HERSHELL, and LORD MACNAGHTEN.)

LORD PROVOST, ETC., OF GLASGOW v. FARIE.—THE CLAY UNDER THE CORPORATION'S RESERVOIRS.

This was an appeal from the decision of the Court of Session (First Division), reversing a judgment of the Lord Ordinary. It appeared that in 1871 the appellants, under the provisions of the Glasgow Water-Works Act, compulsorily purchased from the respondent a quantity of land, upon which they subsequently constructed two large reservoirs for the purposes of their water-works. The price paid for the land was £11,000; and the purchase was made under the general provisions of the Act, whereby the property in the coal, slate, ironstone, and "other minerals," which might be beneath the land purchased should remain in the seller, and that they should not be paid for by the purchasers of the surface soil until the seller should give notice of his intention to work such minerals. Beneath the land acquired by the appellants there was a large quantity of clay and in 1885 the respondent gave the appellants notice of his intention to work the clay as one of the minerals reserved to him under the Act. The appellants thereupon denied that clay was a mineral so reserved; and asserted that the property in it had passed to them when they purchased the surface of the land. Litigation having arisen between the parties in consequence of this dispute, the Lord Ordinary decided in favour of the appellants; but his decision was reversed by the First Division of the Court. The case was argued some time ago, when judgment was reserved. This was given to-day.

The ATTORNEY-GENERAL (Sir R. E. Webster, Q.C., M.P.) and Mr. BALFOUR BROWNE, Q.C., appeared for the appellants; Sir HORACE DAVEY, Q.C., and Mr. E. W. BRYNE, Q.C., for the respondent.

The LORD CHANCELLOR, LORD WATSON, and LORD MACNAGHTEN were of opinion that the clay in question formed part of the surface of the land, and that the right of working it had not been reserved to the seller when the property was acquired by the appellants. They thought the judgment of the Court below must therefore be reversed, and that of the Lord Ordinary restored.

LORD HERSHELL dissented; being of opinion that clay came within the term "minerals," the right to work which was reserved to the seller under the general provisions of the Act. The reservation must, he thought, be taken to extend to all such bodies of mineral substances lying together in seams, beds, or strata as were commonly worked for profit, and had a value independent of the surface of the land.

Accordingly, by a majority, the judgment was reversed, with costs.

HIGH COURT OF JUSTICE.—CHANCERY DIVISION.

WEDNESDAY, AUG. 8.

(Before Mr. Justice KEWICH.)

ARNISON AND OTHERS v. SMITH AND OTHERS.

THE CITY OF GENOA WATER-WORKS COMPANY, LIMITED.

This was an action brought by Mr. Joseph Arnison and 53 other plaintiffs, debenture stockholders in the City of Genoa Water-Works Company, Limited, against Mr. Gordon Smith, the promoter of the Company, and the Prince of Mantua and Montferrat, Admiral Sir E. A. Inglefield, Colonel Hughes-Hallett, Sir Kingsmill Grove Key, and Messrs. H. C. Maudslay, H. F. Giles, and J. Kinloch Malcolmson, the original Directors of the Company. Of the 54 plaintiffs, 12 failed to appear at the trial, and two died before the trial. The remaining 40 appeared as witnesses in support of the case alleged in the one statement of claim delivered on behalf of the 54 plaintiffs. The Company was incorporated in 1886 as a limited liability Company, with a nominal share capital of £300,000, divided into 60,000 shares of £5 each. On Nov. 30, 1886, defendants, on behalf of the Company, sent out a prospectus inviting the public to subscribe for the issue of £150,000 of 6 per cent. debenture stock in the Company. The prospectus contained the following statement:—"Share capital, £300,000, in 60,000 shares of £5 each, of which 40,000, representing £200,000, has been already subscribed." The plaintiffs' case was that this was inaccurate, not more than seven shares in the Company having been taken up or subscribed for at the date of the prospectus; and even in March, 1877, not more than 57 shares had been taken up, upon which only £265 had been paid. The plaintiffs, relying on the representations, and believing them to be true, applied for and became the holders of certain portions of the debenture stock, amounting in the aggregate to £30,200; and they claimed damages for the deceit alleged to have been practised upon them.

The defence was that the defendants made the statements in the prospectus *bona fide*, believing them to be true.

Mr. RALPH NEVILLE, Q.C., Mr. J. F. OSWALD, and Mr. W. BAKER appeared for the plaintiffs; Mr. STEWARD BRICE, Q.C., and Mr. R. BRAY for the defendant Gordon Smith; and Mr. WARMINGTON, Q.C., Mr. F. THOMPSON, and Mr. ALEXANDER for the other defendants.

Evidence having been given at considerable length on both sides,

Justice KEKEWICH, in giving judgment, described the case as a painful and a novel one. Here, he said, 53 plaintiffs combined together to bring an action against the Directors of a Company for misrepresentations in a prospectus; and the point he had to decide was whether there had been deceit in asking people to subscribe for debentures, and whether the statement that £200,000 of shares had been already subscribed for at the time of the issue of the prospectus was true. He must confess he thought the word "subscribed" had been improperly used; and he was further of opinion that there had been concealment as to the real facts of the case. Under all the circumstances, he came to the conclusion that the plaintiffs had made out their case, and were entitled to judgment, with costs as against the defendants. He must, however, make an exception with reference to the order, and that was with regard to the twelve plaintiffs who did not appear. Their actions would be dismissed, and they would pay defendants' costs.

An order was made accordingly. The successful plaintiffs were entitled to the difference between the actual value of the stock which they were deceived into purchasing, and the price which they paid for it. There were no means of assessing this then; and it was referred to Chambers.

Miscellaneous News.

THE EXAMINATIONS IN "GAS MANUFACTURE."

We have been favoured by the Organizing Director of the City and Guilds of London Institute for the Advancement of Technical Education (Sir Philip Magnus) with a list of the successful candidates in the examinations in "Gas Manufacture," which, as our readers are aware, form part of the scheme of Technological Examinations conducted by the Institute every year. It is as follows:—

HONOURS GRADE—

First Class.—Herring, W. R.—First Prize: £5, and Silver Medal.

Bromley, J. F.—Second Prize: £5, and Bronze Medal.

Second Class.—Clark, Geo. H.; Cleland, Alex. M'I.; Simmonds, H.

ORDINARY GRADE—

First Class.—Bancroft, F. J.

Botley, C. F.—First Prize: £3, and Silver Medal.

Helps, D. H.—Second Prize: £3, and Bronze Medal.

Sayner, G. S.—Fifth Prize: Bronze Medal.

Smith, A., jun.—Third Prize: £2, and Bronze Medal.

Sutcliffe, E. J.—Fourth Prize: £1, and Bronze Medal.

Second Class.—Graham, M.; Hall, L. G.; Hearson, W.; Hiller, H. K.;

Holliday, J.; Murray, J. W.; Rudge, H.; Stone, G.;

Surman, W.; Whyte, W.

THE GASLIGHT AND COKE COMPANY.

HALF-YEARLY MEETING.

The Half-Yearly General Meeting of this Company was held last Friday, at the Chief Office, Horseferry Road, Westminster—Colonel W. T. MAKINS, M.P., in the chair.

The SECRETARY and GENERAL MANAGER (Mr. J. Orwell Phillips) read the notice convening the meeting, and it was agreed to take as read the report of the Directors, with those of the chief officials of the Company (which were given in the JOURNAL last week), and the accounts for the half year ending June 30 last, the principal portions of which appear elsewhere today (see pp. 296-7).

The GOVERNOR: I have now to move the formal resolution—"That the report and accounts be received and adopted;" and I hope in this warm atmosphere that it will not be necessary to detain you very long. The report, which you have all received, expresses in short phrases the history of the Company during the past half year; and though that history has been uneventful, I think you will agree with me in regarding it as eminently satisfactory. Last half year, in addressing you, when moving the same resolution, I said that I thought then, speaking of the report for the half year ending December, 1887, that was the best report we had ever had the pleasure and privilege of laying before the shareholders. On this present occasion I can repeat that, because this report and these accounts are, if anything, still better than these we submitted last half year; and in one respect they are certainly very much better, as we recommend an additional $\frac{1}{2}$ per cent. dividend. My usual practice has been to give you the comparative figures, in order that you may see at a glance the differences in working compared with the corresponding half of the previous year. We have in favour of the accounts for this half year, as against the corresponding period of 1887, an increase in meter and stove rental of £768; in the amount received from coke, of £14,122; from breeze, of £49,911; and, in the item of tar and tar products, the large increase of £15,430. This, with a small increase of rent of £61, makes an increase in the income of £35,378. Well, then, on the other side, against the income for this half year, there is a loss on gas of £81,318; and on ammoniacal liquor and sulphate of £7094—the total loss in income for the half year being thus £91,412. Of course, this seems a very large amount; but you will at once perceive that it is accounted for almost entirely by the reduction of 3d. per 1000 cubic feet which took effect from Jan. 1 last. We have been urged very often to take more rapid strides in the way of reducing the price of gas. We have been told frequently—especially by my friend Mr. Livesey—that reduction of price means increase of consumption. I have had occasion to point out to him and to the meeting several times that this is not so in our case. It is not an invariable rule; and in the past half year, the general experience of the Company has been borne out. Our increase for the half year, in spite of the reduction of 3d. per 1000 cubic feet, has been only at the rate of just below 2 per cent.—1.94 per cent.; so that the reduction, large as it is, in the cost to the consumer has not as yet made an appreciable difference in our receipts. To us the cost of the 3d. reduction ought to have been, if there had been no increase in the consumption, £107,280—that is to say, if we had only sold the same amount of gas as in the corresponding period of the previous year. As a matter of fact, the increased consumption gave us £22,962 more. Therefore the amount of £107,000 which we stood to lose was reduced to £84,000. This, I think, is fairly satisfactory, because these changes of price do not take effect at the moment. People do not find out, until their bills go in, that there has been a reduction of price; and they do not correspondingly

increase their consumption. But, looking at the fact that so much of our gas is now used as fuel—for manufacturing purposes, engines, and also for warming and cooking purposes—a reduction of 10 per cent. must tell eventually; because a manufacturer who can get his motive power at 10 per cent. less cost, is always inclined to increase his business. That is so far as regards the income. Then, with respect to our expenditure, our coals have cost us £8297 less for the half year. This I believe you will agree is highly satisfactory, especially as we have used a greater quantity of coal in producing a larger amount of gas. The cost of coal this half year is peculiarly pleasing; because the gross price per ton is 12s. 0.7d. against 12s. 4.30d. The residuals have produced 7s. 6.69d. against 7s. 0.43d. The total net cost of the coal, therefore, this half year has been 4s. 5.38d. per ton, against 5s. 3.52d.—the largest reduction I ever remember in a half year. This accounts for the decrease of £8297 in the amount we have paid for our coals. Wear and tear on manufacture is about £1000 down; salaries and wages are £1832 less; wear and tear on distribution is £5860 down; meter and stove repairs have cost less by £5320; the item of public lamps shows a decrease of £700; rents are £200 less; and law charges are £3599 down. Of course, this is because there has been a little lull in the litigation. The expenses connected with the public testing stations are £149 less. We have therefore in favour of this half year, by the reduction in expenditure, £28,591, and also a sum of £2700 for preference dividend and interest on loans—making the total amount in favour of this half year, against the corresponding period of last year, £66,680. Then, I have given you, on the other side, £91,000 loss on gas and liquor; and in addition our salaries for manufacturing are £200 np. Manufacturing wages are £3900 np; purification is £2600 np; and various small items bring the total debit to the account to £8574. Then we have to add to this the excess of $\frac{1}{2}$ per cent. on the ordinary dividend, which amounts to £20,535, which gives altogether against the half year £120,521. The figures I gave you in favour being £66,680, the net debit for the half year is £53,841. Therefore, though we stood to lose, as I told you, £104,000, the half year is only £53,000 worse than the corresponding period of 1887. The charge for wear and tear, distribution, rates and taxes, and management are practically the same as they were; and therefore I need not go through the figures, as they vary so little that I should be only wearying you. The item of law has given us £2000 to the good, or something over $\frac{1}{2}$ d. per ton; and annuities are £1000 higher. Two or three of our older men have been pensioned off, and we have saved their salaries, though while we get the saving in salaries, it has raised the annuity fund to this extent. That is a measure not only of humanity, but of economy, because we get the work done by younger men at less remuneration; and we enable the men who are past work to retire into private life without being utterly deprived of their subsistence. With respect to the question of increased consumption, I have told you that it has been in the past half year 1.94 per cent. This at first sight might appear discouraging; but I am happy to say, with reference to the present half year, as far as it has gone, the increase has been very satisfactory. We are among those who might be looked upon as misanthropic individuals, who always benefit by the misfortunes of their fellow-creatures; and the wet, cold, and dull weather which has been so oppressive to the public at large has brought a large amount of grist to our mill. The accession of the late summer that has come upon us will probably tell upon our increase; but it has already arrived at such a figure that we may look with complacency on the prospects for this half year. You will have noticed that coke is a very satisfactory item. The addition of £14,000 in the half year from coke is a fact full of comfort; and I do not think we have seen the best of it yet. I believe that the present half year will show results quite as satisfactory, if not more so than in the past half year. The same remark, in a modified way, applies to breeze. I do not know that I need trouble you with any more figures with reference to the working of the half year. If I have omitted to give anything in the way of statistics, I shall be happy to supplement what I have already said by way of answers to questions at the end of the proceedings. The proprietors will remember that I mentioned an experiment which we had tried with regard to supplying gas to small dwellings—cottages, tenements, and so on—on the principle of finding the fittings and charging a rental for them, so as to bring the use of gas into the cottages and smaller dwellings in the East-end of London. Of course, the experiment has not yet progressed very far; but I can give you the results up to the present. We have laid on services to 96 houses and given them a supply of gas; and 85 out of the 96 have been lighted for the full period of three months from March to June. Of course, the meeting will remember that this is one of the lightest quarters of the year; and therefore the figures are not very large. The rental we have received has been £29 13s. 10d. This gives an average of, as near as possible, 7s. per house, or at the rate of 6d. per week, including the rental of fittings. I think that when the British workman can get his rooms lighted and warmed, and his fittings put in, for a payment of 6d. a week, without any trouble to him, we have a right to look for a very large development in this form of business; and, of course, it is a business which has great capabilities. When I add that there has been no trouble whatever in collecting the money from the working men, and that there has been no loss and not a penny of bad debt, we can look on the experiment as satisfactory, and as encouraging us to proceed in the same way. These 96 houses I mentioned are all in Silvertown. We now propose to adopt the same system in other parts of our district; and I hope I shall be able, at our next meeting, or the meeting after, if I am in the chair, to give the results of this further experiment. With regard to stoves, we are going on steadily. We have now 7322 stoves out that we know of—that is, our own stoves, those issued by the Company. The rental of the stoves for the half year has been £2283, against £1974. This is very satisfactory, because what we want is day consumption, so that we may utilize our plant during the 24 hours round. Of course, lighting is our mainstay; but the fuel business is progressing, as you see by these figures, in a very satisfactory way. It is the more satisfactory because, with regard to fuel, we have no competitor. The electric light we must regard as a competitor, as far as it goes, for illuminating purposes; but for fuel we have no competitor, except, of course, the ordinary coal and coke. I am reminded by the Deputy-Governor that you must not assume from what I have said that our lighting business is bad, because our meter-rental, as well as the stoves, shows an increase. I only meant to say this—that the fuel business is peculiarly satisfactory, and the lighting is equally satisfactory; but it has not that element of freedom from competition which fuel has. I think I have now dealt with all the figures which I need trouble you with. Perhaps some of the proprietors naturally look at the price of our stock from time to time; and they may have seen a sudden drop the other day. As far as we can understand, this fall occurred through the introduction of a new Electric Lighting Company—introduced to the public by some well-known scientific and other names. As far as my experience goes, the only people who have so far derived any good from electric lighting have been the people who have sold the machinery. I know of no company which is paying a dividend or interest on its lighting business; and, as I told some of my friends in this new Company, they have a long uphill game before they can make £25,000 a year to pay even 5 per cent. on the capital they are asking for.

However, the electric light will progress, and ought to progress; and we ought to feel no jealousy for it. There is plenty of room for lighting by the electric light, by oil, and by our gas; but I hope no proprietor will be so unwise, under the influence of panic, or a flaming advertisement by a new company, as to throw away his stock at a reduced value. You must look at the position of this Company. You have a 10 per cent. dividend, with a maximum price of 3s. 9d.; but your price is only 2s. 9d. You thus have 1s. margin in price before your 10 per cent. can be touched. In addition to this, you have £887,000 of undivided balance, reserve fund, and insurance fund; so that you have two years' dividend in hand at the full rate, besides the 1s. extra you might charge for gas if it were necessary for you to do so. I do not, however, suppose there will be any question of increasing the price of our gas. On the contrary, looking at the prospects of the present half year, and the satisfactory financial position we now hold, it will be our duty, I expect, to announce to the proprietors next year, when the coal and wine dues fall in, a further reduction in price, with a corresponding increase in the dividend. I have always been very careful not to prophesy, and I do not state this as a fact. But I say that the inferences, from the condition of our accounts and of our working, lead me to believe that this will be the result. *Festina lente*—go gently—has always been our motto here. We do not want to rush the price down by leaps and bounds. We want to make our position as sure as we can. We have found this policy right in the past. It is a policy which has been endorsed by our proprietors in the past; and I feel sure it will be endorsed by them in the future. Our neighbours in the South propose, I see by their report, to give the whole benefit of the abolition of the coal and wine dues—which in our case would be £91,000—to the consumers. I want to know before I deal with this £91,000 how it will come out. In the first place, we shall have, as I said last half year, if we get this duty off the coal, to make some reduction, no doubt, in the price of the coke which we sell. Then there may be taxes reimposed in the place of the dues taken away; and whatever the margin may be, I cannot tell. When we do get at the margin, however, it appears to me that our duty is to deal with it on the principle laid down by the Act of Parliament. If the sliding scale is good for anything, it ought to be worked both ways. The £91,000 would be equivalent to 1½d. per 1000 cubic feet in the price of gas, if we gave the whole of it; but as I was saying I do not think we are called upon, in a spirit of philanthropy, which is not business, to inveigh the principle of the sliding scale, which has been adopted by Parliament as a just and fair means of dealing with gas companies and their consumers. We are not called upon to invalidate this, or to go against the principle of that settlement, by devoting this money altogether to the consumer. In addition to the coal dues coming off, I am happy to say that we have made our contracts for 1889, as far as sea-borne coal is concerned, at a reduction of about 4d. per ton all round. This will give us a very handsome addition to our revenue—to the tune of about £25,000. Taking this into consideration, taking the coal dues into consideration, and remembering the increased and improving trade of the country, which reacts on our residual products, and will no doubt also add to our gas consumption, I think I am not in want of justification for my modified form of prophecy as to a reduction in the price next year, and a further increase of dividend. There is one other question which has been raised in the report—that is our litigation with the South Metropolitan Gas Company. No one can regret this more than the Court of this Company does; but we were not the attacking party. The litigation was forced on us, unless we were to sit down with a loss of £4000 a year, and meekly bear it. We have prosecuted the litigation up to the present point without success; but the judgment of the Court of Appeal decided us to go to the House of Lords. [The Governor here quoted from the judgments delivered in the Court of Appeal by Lords Justices Lindley and Bowen, which were given in the JOURNAL for Feb. 28 last, p. 377.] In the face of these judgments, was it, I ask, possible for us to refrain from carrying the litigation to the House of Lords? We were supported by the opinion of Counsel; and we were told that it was our duty to take the opinion of the highest Court. This is a question which affects the districting of the Companies, and is vital to the lighting of the whole of London; and, however deeply we may deplore being at loggerheads with our neighbour, and the money spent on law, yet it is a matter of such great importance, that I think we are bound to get a final judgment on it, and abide by it, whatever it may be. You will notice a small footnote at the end of the accounts signed by Mr. Parkes, our Official Auditor, in which he says: "A forfeiture incurred during the half year, amounting to 5s., must be borne and paid exclusively by and out of the divisible profits of the Company, and by way of reduction of dividend." Well now this fine of 5s. arose in this way: We were charged by the Chief Gas Examiner with being on one occasion below our parliamentary standard of illuminating power. We demurred to the charge, and appealed against it; and though we brought plenty of evidence, the judgment of the Chief Gas Examiner, which is final, was against us; and he declared default to have been made. Then the Metropolitan Board of Works summoned us before the Magistrate, and asked him to inflict a penalty.* The Magistrate was apparently very much surprised by this action of the Board of Works, and asked what was the evidence. There was no evidence to be brought forward. They told him: "You have simply to discharge an official duty. The Chief Gas Examiner has given his certificate that default has been made; and all that you have to do is to inflict the fine." So little evidence was there, that even the very candles by which the test had been made had been either carelessly or carefully thrown away; they were not forthcoming to prove the case against us. The Magistrate expressed his sense of the injustice of the Board of Works by inflicting a fine of 5s., instead of the statutory penalty of 40s., and a sum of 2s. for costs. I think we have great reason to complain of the action of the Board of Works in this matter. The Magistrate also seemed to have the same opinion, that we had a right to complain, because he refused them their costs. But at the very time that they were bringing this charge against us, which they did not support with any evidence, and in which they merely demanded their legal pound of flesh, and told the Magistrate that he had no business to go into the question at all, but that he was simply to inflict the fine—at that very time our neighbours on the south were admittedly, on five occasions, below their parliamentary standard, either in the case of illuminating power or in purity. One would have thought that a consistent body like the Metropolitan Board of Works (laughter) would not have made fish of one and flesh of another; but they abstained entirely from taking any action against the South Metropolitan Company, although they say that that Company's gas, when tested in the Blackfriars Road, showed "a lighting power of only 15·0 and 15·4 candles respectively, instead of 16 candles; and on three days in October the same Company's gas was found to contain ammonia to the amount of 6·6, 4·8, and 5 grains in 100 cubic feet." They go on to say: "It would, in ordinary circumstances, therefore, have been the duty of the Board to bring the matter before a magistrate, and to ask that the forfeitures pro-

vided for in the statute might be imposed on the Company. It so happened, however, that the South Metropolitan Gas Company was about that time giving facilities to the Board's officers, who were, under the instructions of a Committee of the Board, making experiments for the purpose of determining what was the most trustworthy standard of light to be used in photometry; and, as these facilities could not be claimed by the Board, and were given by the Company as an act of courtesy, it would have seemed ungracious to seek at that time to subject the Company to forfeitures in respect of defects which, although the Chief Gas Examiner was unable to certify that they were unavoidable, were yet, there was reason to believe, not due to culpable negligence. The Board confined itself, therefore, to cautioning the Company, and requesting it to use greater care in future." In the first place, they did not report their action with regard to our Company at all. They passed it over in discreet silence. In the second place, they leave it to be inferred by the public that the South Metropolitan Company were giving facilities which we refused. I can appeal to our Distributing Engineer, and other Engineers, to say that this charge—it was not exactly a charge, but an inference—was without foundation. Every facility has been given by this Company, every expense incurred, and everything done that could be done to facilitate the work of the Referees, and I think this was a most unjust proceeding. It was unfair on its merits; and it was doubly unfair when we take it in conjunction with the action as regards the other Company. However, the Board of Works, as you are aware, is a moribund body; and no doubt it wanted to show a little action before it came to an end. It is a moribund body, and, to paraphrase Sir Walter Scott—

Doubly dying, will go down
To the same vestries whence it sprung,
Unwept, unhonoured, and unsung.

(Laughter.) I think that this concludes all I have to say with regard to the report. I am reminded by the Secretary that a little difficulty arose about the fine of 5s. It is payable out of the dividend, so that, strictly speaking, it ought to have been divided into 8000 parts, and each shareholder should have paid his proportion; but as this would have entailed a considerable amount of work on our staff—who, however, are always very willing to work—I cut the Gordian knot by asking the Secretary to take the whole amount from my dividend. The steam-roller action remains the law of the land; and I think we are not likely to be troubled much more. I have reason to know that the Vestry of St. George's, Hanover Square, are anxious to get a settlement with us something on the lines of the Chelsea agreement; and I have expressed willingness, on the part of the Company, to meet them in that way, so I hope we may come to some arrangement with them. I have now dealt with the whole of the past half year. I have told you what I think about the coming half year; and all that I have to remark in conclusion is this—that the works and the plant of the Company were never in better condition than they are at this present moment. In spite of the reduction in expenditure in the wear and tear and so on, the plant and the works have been kept in perfect condition. I am bound, as a matter of justice, to say that the officers of the Company, from the highest to the lowest, have discharged their duties both faithfully and efficiently to the Company—not only in the past half year, but ever since I have had the pleasure of being Governor of the Company. It is a peculiar pleasure to me to give this testimony in the face of the proprietors, after I have given them such evidence as they have had in the report and in the accounts of the well-being of the Company. I was down at Beckton the other day; and I am very glad to be able to report that things there are going on not only very well as regards the near future of gas and the dealing with the products, but that the welfare of our workpeople there, both spiritually and from a sanitary point of view, is being well looked after. We have a very active Chaplain there, and there are ministers of every denomination, who do all they can for the spiritual wants of our people. They have a cricket-ground, a ciuder-path, and a hall where they have their meetings, concerts, &c. It has been pointed out to me, that, though there is recreation, and the means of recreation in the summer, there is a want which we might supply. They require a tolerably large shed for the winter, for drilling and gymnastics, and a swimming bath, which is almost a necessity down there. I have spoken to the Government Auditor, and he is pleased to regard favourably the proposal I mentioned; and I think if the proprietors as a whole see no objection to the expense, we might very well spend a few hundred pounds, probably £1000 in all, in providing these necessities for the recreation and welfare of our workpeople. Assuming that the meeting agree to this, and that the Board of Trade raise no obstacle, plans will be got on, and the work be done in the course of the next few months. I do not know that I have anything further to add to what I have said; but I must thank you for the kindness with which you have heard my somewhat extended statement.

The DEPUTY-GOVERNOR (Mr. H. C. Ward) seconded the motion.

Mr. JACKSON referred to the abolition of the coal dues; and said he thought that the Company ought not to be outdone in justice to the public. The abolition of the coal dues was a measure intended not to benefit the Gas Companies of the Metropolis, but the ratepayers. With the splendid dividend being paid by the Company the first six months after the last reduction in price, he thought it would be very bad policy, and unlike The Gaslight and Coke Company, if they did not "do the handsome"—in fact, the just thing—in connection with the abolition of the dues. He regarded the report as eminently satisfactory.

Mr. SIMPSON dissented from the view taken by Mr. Jackson, as to what the Company should do with regard to the benefit obtained from the abolition of the coal dues; and he expressed a hope that that gentleman's suggestion would not be acted on.

Mr. GEORGE LIVESLEY: Mr. Chairman, you will never leave me alone. You have done me many good turns; but I am afraid that the remarks you have made this morning will tend possibly to bring me before Lord Herschell for having "squared" the Metropolitan Board of Works; still I am not very much afraid of that. However, there is something to be said on behalf of the Metropolitan Board. The Gas Referees put up a new testing-station, which gave very extraordinary results; and when we were making 19-candle gas, we could hardly show 16 candles there. That accounts for the low tests recorded. I am bound to say that in defence of my own Company.

The GOVERNOR: I have not complained of your Company, but of the Board of Works.

Mr. LIVESLEY: Yes; I know. With respect to the coal dues, I agree with Mr. Jackson most thoroughly; and I put it this way: Philanthropy is not business, as you say; but justice is business. If you were going to Parliament to have your initial price fixed, and the coal dues were to be removed at the time, you could not ask for the present initial price to be renewed; because the abolition of the coal dues is equal to a reduction of 1d. per 1000 cubic feet, and therefore the public would be entitled to that penny. I think this an act of justice, and an act of wisdom. I took rather an active part on the Committee who were opposing the renewal of the coal dues. There were some eminent men on the Committee; amongst them Sir Henry Doulton, who told me repeatedly that the great obstacle to

* See JOURNAL, Vol. LI., p. 475.

the coal dues being abolished was the Gas Companies. Everyone was saying that the abolition of the coal dues would only put more money in the pockets of the gas shareholders, who had now enough; and these members of the Committee said that if it could be shown that the public would get the benefit, this argument for the renewal of the dues would be got rid of. I took upon myself—and in this I was supported by my Board of Directors—to write a letter to the First Lord of the Treasury just at the critical moment, when a deputation was going to see him; and in the course of that letter I stated most distinctly that, as far as the South Metropolitan Gas Company were concerned, the Board would recommend the shareholders not to take the additional dividend to which they would be entitled by the reduction of 1d. per 1000 cubic feet which would result from the abolition of the coal dues. I think that that is a wise thing, and a just thing. I should be the last to go for an abrogation of the sliding scale. But I say that the sliding scale has done for us more than was expected; and it is right that we should at any rate do an act of justice towards the public in this case, and I am quite sure it will redound to our advantage. There is one other matter which I should not have referred to, but for the allusions already made to the unfortunate litigation between us. You have quoted the judgments of two of the Judges; but you have not quoted the judgment of Lord Justice Cotton, who took the most decided view in the judgment. I am not going to discuss that question, as it is still *sub judice*. But it is commonly said in gas circles that everyone knows it is a personal quarrel between Mr. Phillips and Mr. Livesey; and this libel is being uttered against your respected Secretary and myself—that we are urging our respective Companies to go on with this fight simply for personal reasons. I repudiate that, as much in his interest as in my own. I feel after the transcendent services which Mr. Phillips has rendered to the Chartered Gas Company that he would not sacrifice the interests of that Company from any personal feeling whatever; and I say the same for myself. I feel, however, that you take a wrong view of the matter. You say it entirely upsets the districting arrangements. Now these districting arrangements have gone on under this system for 35 years; and whether the decision is given in your favour or is not given in your favour, I do not fear that it will upset or interfere with the districting arrangements to seriously or appreciably affect either Company. I feel that we are travelling the same road, though our horses are not in the same team. It is not a time when Gas Companies should be quarrelling amongst themselves; and I am anxious, and have all along been anxious, to see whether some means cannot be devised whereby we can put an end to this dispute. I am told that you feel sure you will win. Well, there have been two decisions against your view in the Court of Appeal—and I suppose there have been two other decisions—and in addition there is the practice of gas companies for the last 35 years. But suppose you do win, I ask "What will you win?" and if you lose, "What good will it do to us?" My Company do not want to pursue this trial for the sake of gaining the victory over you; and I cannot suppose that you want to pursue the trial for the sake of gaining the victory over us. I believe you are actuated by a desire to have the law settled and defined; and my opinion is that, by the two Boards coming together, we could settle the matter without playing further into the hands of the lawyers. You have been guided by counsel; and I am not going to say anything against counsel. I see you have them on your right and left. But counsel live by litigation; and although I would not suggest that the very eminent men engaged in the conduct of your case are actuated by this motive, still they are like doctors. If a doctor has a very serious case—such as a compound fracture or some complication of diseases—his professional pride is aroused, and he regards it as a most interesting case to him, however much the reverse it may be to the poor patient. So in this case, I fancy that counsel are urging you on because they think this a very interesting case, and that it should be carried to the highest tribunal. I am not very anxious about it—my Company has been passive from the first; we are simply waiting for any decision that may be come to. But I think it will be better for the two Companies to put their heads together, and avoid any further litigation.

The Governor: Mr. Jackson has referred to the coal dues. All that I have to say with reference to the matter is that we shall, in justice to the public, and in our own interest, reduce the price of gas as soon as we possibly can. But I see no reason why we should "earmark" the special amount which we may get for that purpose—the balance when the thing is worked out. Mr. Livesey has argued that the abolition of the coal dues was not foreseen when our initial price was fixed. I traverse that view altogether. The coal dues were not levied in perpetuity, but for a given purpose, and for a given time; and those who fixed the initial price of gas knew that these dues had a certain time to run, and they were probably able to estimate what the value of the coal dues was. As a matter of fact when the dues expired, they were extended for a short time, so as to free the London bridges. As a matter of principle, I do not see the justice of "earmarking" the amount, and handing it to the public simply because it comes out of the abolition of the coal dues. However, we must take our own course with respect to that. It is a mere matter of policy; and in the end it makes no difference, because whether the money comes from that source or any other source, we shall, when we have the money in hand, reduce the price of our gas. The only bit of grit in the wheel is the litigation between ourselves and the South Metropolitan Company; and it could all be put an end to in a moment. We say that Mr. Livesey has done a little bit of "poaching," and got into our district to the tune of £4000 a year. If he will pay us back the amount he has received, we will not go on with the case. Either the revenue belongs to him or to us. He says it belongs to him, and he has got possession, and that is nine points of the law. What we have to do is to see if the law will not give us back what we think is our own. If he thinks that the case should not go on, he has only to say, "I made a mistake. I took some of your revenue. Here it is back again." I may say that there will be no ill-feeling on the part of this Company if the High Court of Parliament and the Peers should give him the verdict, and leave us to bear the loss, which has not seriously incommoded our dividend during the past two years. We are always very happy to meet Mr. Livesey, and discuss this or any other matter with him; but those are the lines on which we should have, I think, to discuss it, in the interest of our consumers and our proprietors. I give Mr. Livesey now a direct invitation if he will come and discuss it. I would, however, ask him to postpone the matter for a fortnight or three weeks, as some of us want to go away for a little change.

The resolution was then put to the meeting, and at once carried unanimously.

On the motion of the Governor, seconded by the Deputy-Governor, the various dividends were next approved.

The Governor: That concludes the business of the meeting. I might perhaps correct what was apparently an error in one remark I made. In dealing with the "for and against" for the past half year, as compared with the corresponding period of 1887, I said that £53,841 was the net

debit. But that is only on that one account; the real deficiency is only £36,018.

A cordial vote of thanks to the Court of Directors and to the officers, for their able conduct of the Company's affairs in the past half year, was then carried unanimously.

The Governor: I am sure, ladies and gentlemen, that we are very much obliged to you for passing this resolution. We accept it with gratitude, both for ourselves and officers. We are one and all, as I have said before, actuated with but one desire—that is to make the Company in the future as great a success as it has been in the past.

The meeting then separated.

THE ACCOUNTS FOR THE HALF YEAR ENDING JUNE 30, 1888.

In the JOURNAL last week we gave the reports of the Directors and Chief Officials of the above Company for the half year ending June 30 last. We now reproduce the accounts for this period; but, following the plan adopted with the accounts for recent half years, we shall only indicate the alterations, if any, in those portions which are not subject to much variation—giving the rest of the statements in full.

Nos. 1 and 2 are statements of stock, share, and loan capital, the totals of which stand as in the previous account—viz., stock and share capital, £8,103,000; loan capital, £2,156,000.

No. 3 is the capital account, which, as far as the receipts are concerned, has not undergone any change; the total being £10,690,900 (comprising the amounts of share and loan capital above named, and £401,900 of premium capital). The expenditure is shown in the following items:—

Expenditure to Dec. 31, 1887	£10,236,324 15 7
Expenditure during the half year to June 30, 1888, viz.:	
Lands acquired, including law charges	£955 1 6
Buildings and machinery in extension of works	539 15 2
New and additional mains and service-pipes	4,038 11 6
Do. do. meters	215 16 7
Do. do. stoves	2,852 9 5
	£8,601 14 2
Less—Depreciation of meters	£3,618 0 0
Do. stoves	1,839 0 0
	5,457 0 0
	3,144 14 2

Balance of capital account	£10,239,469 9 9
	451,430 10 3
	£10,690,900 0 0

Nos. 4 and 5 are the revenue and net revenue accounts. These are given on the opposite page.

No. 6 is a statement showing how the Directors propose to appropriate the balance applicable for dividend. It is as follows:—

June, 1887.	
£55,851 .. Net balance brought from last account	£280,293 16 8
436,084 .. Net revenue for the half year	402,728 0 2
	£683,021 16 10
£491,835 ..	
(12½ per cent.) A dividend on the ordinary stock—	
334,924 ..	13 per cent. on £5,468,600
	355,459 0 0
£156,961 .. Balance carried to next account	£277,566 16 10

Nos. 7 and 8 are the reserve and insurance funds accounts. The former shows that the balance of the reserve fund on Dec. 31 last was £436,788 14s., which was increased at the close of the past half year to £495,252 5s. 1d. by the addition of £5463 11s. 1d., interest on the amount invested. The insurance fund stood at £78,092 7s. 2d. at the end of 1887; at June 30 last it amounted to £80,115 8s. 6d.

No. 9 is the depreciation fund account. It stood at £31,203 12s. 7d. at the date of the preceding report. At the end of June last it had been raised to £32,417 6s. 1d., by the addition of £750 transferred from the revenue account, and £463 13s. 6d. received as interest.

Nos. 10 and 11 are as follows; and Nos. 12 and 13 are given on the opposite page.

No. 10.—STATEMENT OF COALS USED, &c.

Description of Coal.	In Store, Dec. 31, 1887.	Received during Half Year.	Carbonized during Half Year.	Used during Half Year.	In Store, June 30, 1888.
	Tons.	Tons.	Tons.	Tons.	Tons.
Common	951,515	779,207	886,998	827	82,897
Cannel	44,418	2,860	9,804	..	57,474
Total	335,933	782,067	896,802	827	120,371

No. 11.—STATEMENT OF RESIDUAL PRODUCTS.

Description.	In Store, Dec. 31, 1887.	Made during Half Year.	Used during Half Year.	Sold during Half Year.	In Store, June 30, 1888.
Coke—chaldrons	35,333	1,087,005	208,432	890,458	23,448
Breeze—chaldrons	12,711	120,683	52,404	75,004	6,016
Tar—gallons	603,123	10,003,787	9,178,948	927,518	505,444
Ammoniacal liquor—butts	15,157	265,802	261,120	10,862	8,977

SOUTH METROPOLITAN GAS COMPANY.

THE ACCOUNTS FOR THE HALF YEAR ENDING JUNE 30, 1888.

In the last number of the JOURNAL (p. 252), we published the report of the Directors of the above Company, which will be presented at the half-yearly meeting of shareholders to-morrow. We now give the accounts, showing the working of the undertaking in the six months ending June 30 last, the most important portions being reproduced in full on p. 298, and the following being an epitome of the remainder:—

Statements Nos. 1 and 2 show the amount of share and loan capital at the end of June. The former stood at £1,991,500, and the latter at £561,840; as against £1,977,062 and £518,540 at the close of last year.

Statements Nos. 3, 4, and 5—the capital, revenue, and profit and loss accounts—are given in full.

Statements Nos. 6, 7, and 8 show the positions of the reserve, renewal and insurance funds. The reserve fund stands at £220,544; having been increased by £185 received on the conversion of Consols, which sum remains to be invested. The renewal fund has been raised from £6737 to £6850, by an amount of £112 received for interest. The insurance fund has been increased in a similar way from £39,320 to £40,235.

Statements Nos. 9 to 11—furnishing particulars as to the manufacturing operations of the Company—are given in full; as is also No. 12, the general balance-sheet.

ACCOUNTS OF THE GASLIGHT AND COKE COMPANY FOR THE HALF YEAR ENDING JUNE 30, 1888.

BRENTFORD GAS COMPANY, LIMITED.

The Half-Yearly General Meeting of this Company was held last Friday, at the Charing Cross Hotel—Mr. Howard C. Ward in the chair.

The SECRETARY (Mr. W. Croxford) read the notice convening the meeting; and it was agreed to take as read the Directors' report and accounts, a reference to which appeared in the JOURNAL last week (p. 252).

The CHAIRMAN said it was his duty to move, as usual, the adoption of the report and accounts. In bringing them to the shareholders' notice, he should have very few words to say, as they spoke well for themselves. He had great pleasure in laying them before the proprietors, as it was one of their red-letter days when the Board were enabled to announce the declaration of a larger dividend by $\frac{1}{2}$ per cent. than they had done in either the last or the corresponding half year of 1887. From the time they reduced the price of gas to its present price in the district—that was the last 2d. reduction—they had not had any dividend under the sliding scale until that day. They had given the whole of the benefit to the consumers as soon as they could. Now it was the shareholders' turn, and they had the $\frac{1}{2}$ per cent. to which they were entitled under the provisions of the Act of Parliament; and he (the Chairman) would put before the meeting a resolution to authorize the payment of a dividend at the rate of $11\frac{1}{2}$ per cent. per annum upon the ordinary stock. The shareholders would see that in almost every particular—he thought he might say in every particular—the accounts presented very favourable results. There were very few items indeed which were in any way against the Company. They had certainly spent £282 more in coals, but they received in respect of that sum, in the way of gas-rental, £2595; so that he thought they would agree that this sum of £282 was very well and profitably laid out. In every particular he believed they were better. In the wear and tear on their manufacturing plant, although they had expended upon it every penny that he thought Mr. Morris (their Engineer) in his ingenuity could fairly lay out, they had still spent £706 less than in the corresponding half year. In the wear and tear in distribution, they spent £399 more; but in this sum was included an amount of £250 which had arisen from an accident that occurred, not by any neglect of the Company or of any person connected with it, but by that great bugbear of all gas companies—the steam-roller. The steam-roller of the parish of Hammersmith went up a street where there is one of the Company's mains, and the pipe was broken, and an explosion took place, by which damage was done to certain houses. Of course, the Board all believed they had a very excellent case for legal proceedings against the Hammersmith Vestry; but, although he (the Chairman) was a lawyer, he was not particularly fond of the law, and if they could manage to keep good friends with their neighbours upon reasonable terms, he thought it better to settle the thing without going into Court, and not spend their money. This extra amount of £399 on wear and tear in distribution comprised the amount they expended in restoring the houses and shops that were damaged. The general result of the half year was this—that they had a gross profit of £31,774 7s. 1d., as against £27,056 for the corresponding six months of 1887; and after they had declared the $11\frac{1}{2}$ per cent. dividend, the $8\frac{1}{2}$ per cent. upon the new stock 1881, and met the preference charges, they had on the half-year's working a surplus of £647 10s. 8d., which he considered an extremely good thing, and for which, of course, they were mostly indebted to the intelligence and energy of the officers of the Company. The net result of the whole thing was this—that the Board would pay the dividends and carry forward £35,698 18s. to the undivided profit account. The value of the residual products had been going up. Some people might think that they had now come to the time when the public would be looking for a reduction in the price of gas, because of the approach of the abolition of the London Coal and Wine Dues; but he (the Chairman) was not at all sure of the effect this might have upon the Gas Companies. It was not at all clear to him that it would be all profit to the Company, because it was perfectly plain that if these dues were taken away from the people who had to find the money, and expended it for the public benefit, the money would have to come from some other source, and they would be taxed in some other way; and this amount of money would have to be raised, of which they would have to pay a considerable part. Besides this they would lose a good deal of money on the coke, because their coke contractors and the people who took the coke had, in connection with this, a drawback of 1s. a ton from the Corporation; and when this was gone they could not pay the Company the same price for the coke which they paid now. And therefore, adding this and this together, they hardly knew how the abolition of the dues would affect gas companies. They would not affect them so as to benefit them as much as was supposed. The Board's decision, and their duty and wish, was to reduce the price of gas as soon as they could; and it would be their duty to the consumers and to the interest of the shareholders. The Company had been going on in a marvellous way. He saw the capital had increased 58 per cent. in the last ten years. The gas sold had increased just cent. per cent. This was very good indeed. The price of gas had been reduced 20 per cent. The coals carbonized had increased 78 per cent. The gas sold per ton of coal carbonized showed that Mr. Morris, who was their Engineer ten years ago—and he (the Chairman) hoped would be so in ten years' time—had managed to work such improvements that he was now able to manufacture much more gas from the coal than he was able to do ten years ago. He concluded by moving—"That the report and accounts be adopted and entered on the minutes."

Mr. J. ORWELL PHILLIPS seconded the motion, which was at once carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. PHILLIPS, dividends were declared at the rate of 5 per cent. per annum on the 5 per cent. preference stock, at the rate of $11\frac{1}{2}$ per cent. per annum on the consolidated stock, and at $8\frac{1}{2}$ per cent. on the new stock, 1881, payable on the 1st prox.

Mr. MATTHEWS proposed a vote of thanks to the Chairman and Directors.

Mr. LAXTON seconded the motion; remarking that he thought the Board had done right in recommending the additional dividend to the shareholders. He was a lawyer, and entirely concurred with what the Chairman had said in regard to litigation. It was very wise indeed on the part of the Board, in the present state of litigation, to settle the matters to which the Chairman had referred.

The motion having been unanimously carried,

Mr. LAXTON proposed, and Mr. GIVENS seconded, a vote of thanks to the Auditors (Messrs. W. Bradfield and J. W. Field); and it was agreed to.

A vote of thanks was accorded to the officers of the Company; and the proceedings then terminated.

PROPOSED PUBLIC LIGHTING OF FORMBY WITH GAS.—Last Friday, a three days' poll with regard to the lighting with gas of the roads in the Formby district was brought to a close. Up to the opening of the poll on that day the figures were 89 against gas, and 12 in favour of the scheme. At the close, the presiding officer announced the result of the polling as follows:—For gas, 31; against, 175.

BIRMINGHAM CORPORATION GAS SUPPLY.

WORKMEN'S HOLIDAYS.—SALES OF COKE.—SALARIES OF OFFICIALS.

At the Meeting of the Birmingham Town Council last Tuesday—the Mayor (Alderman Pollack) in the chair—the report of the Gas Committee, an abstract of which was given in the JOURNAL for the 3rd ult. (p. 33), was brought up for approval. In the course of the discussion, questions were introduced reflecting upon the administration of the department.

Mr. BISHOP proposed the adoption of the report. Alluding to the subject of workmen's holidays, and to the recommendation of the Committee that the memorial received from the workmen at the Windsor Street station should be "referred to the General Purposes Committee for the purpose of obtaining information as to the practice followed in the other departments," he said that this manner of dealing with the memorial was recommended because its promoters were in error as to the custom of other departments, on which, in a measure, they founded their case. The Committee were asked to depart from a principle which had hitherto been carried out in respect of the holidays in the Gas Department. They were of opinion that the best course to adopt would be to refer the matter to the General Purposes Committee, so that they might bring forward some general scheme acceptable to all departments.

Mr. BLOOR moved, as an amendment—"That the prayer of the memorialists be and is hereby conceded; and the Gas Committee be authorized to make the necessary arrangements for such holiday." He said he was surprised that a question between employers and employed should be referred to a Committee not concerned with the matter. It seemed to him that the proposal was simply an attempt to shuffle out of the application. In the same department the chief officers had three weeks' holiday; and even the gatekeeper had three days' holiday each year. The men alluded to in the memorial worked, on an average, 78 hours a week.

Mr. WHATELEY, in seconding the amendment, said it was evident that the nature of the men's work alone entitled them to a week's holiday.

Mr. STRINGER protested against the suggestion that the Gas Committee were trying to "shuffle" out of their responsibilities. In many respects he thought the question could best be dealt with by the Public Works Committee. There was also the ratepayers' view of the matter to be considered. He estimated that if the request of the memorialists were carried out, there would be an additional cost of £1650 a year to the town, or a total of £3000 in respect of the holidays of Corporation employees.

Mr. LOWE said that in his opinion the Public Works Committee could best deal with the subject.

Mr. GREEN remarked that the cost of granting the memorials would be about £800 a year, and not £1650, as Mr. Stringer had stated.

Mr. LOUGHTON suggested that the following rider should be added to the proposal of the Committee:—"And that in the meantime the Gas Committee gives to the carbonizers the week's holiday asked for, proportionate to their term of employment; but that this should not be taken as a precedent."

Mr. MARTINEAU said he could not approve of one Committee regulating the holidays to be given to the workmen under another Committee; and therefore, he should vote for the amendment.

Mr. BLOOR observed that he would accept Mr. Loughton's suggestion.

Alderman BARRATT moved, as an amendment, that the matter be referred back to the Gas Committee.

Mr. BRINSLEY seconded the amendment.

Mr. LAWLEY PARKER asked Alderman Barratt to accept the following amendment in lieu of his:—"That the question of the two memorials in reference to the holidays be referred back to the Gas Committee to be dealt with by them, and that the Gas Committee be asked to deal with the subject at once." He thought that the matter would become more complicated if it were referred to the General Purposes Committee.

Mr. BEALE said he hoped that Mr. Parker's amendment would be adopted.

Alderman MANTON considered that the discussion which had taken place was a desperate effort to gain a victory over the Gas Committee. The Gas Committee, he said, were prepared to deal as generously with their workmen as any individual member of the Council dealt with his own men; and he was sure that the matter might be left entirely in their hands.

Mr. BISHOP here intimated that he would accept an amendment referring the matter back with instructions to further consider the subject, and to deal with the same in such manner as the Committee might think advisable. In accepting this, he said that the Committee should be called together immediately; and the question of the men having a week's holiday should be at once considered.

Mr. BOWKETT inquired if Mr. Bishop would accept the following addition to the amendment:—"And that in the meantime the prayer of the memorial from those employed in the carbonizing department be granted." If the addition were adopted, he would second the amendment.

Mr. BISHOP said he could not accept the addition, for this reason—The word "carbonizers" referred to 660 men. The total cost of granting the prayer of the memorials would have been about £1000. He could not promise that the holidays would be granted; but he had every expectation that they would be.

A division was then taken; and Alderman Barratt's amendment as altered was carried, and afterwards adopted as a substantive motion.

Mr. BISHOP, referring to the discussion which had taken place in the newspapers with reference to the sale of coke by the Corporation, said that the Committee had 150,000 tons of coke to dispose of every year. It was impossible to get rid of the whole of this in Birmingham, although the Committee had directed their constant attention to developing the demand for coke in the town. Notwithstanding their utmost exertions, however, they had not been able to sell in the town more than half of the quantity mentioned. In 1877 the town sales amounted to 38,500 tons; and last year 72,000 tons. They had always had to depend on the ironmasters of the Black Country to take the remainder; but unfortunately, through the long depression, the sales to the ironmasters had been a diminishing quantity from 1877. In that year they sold to them 58,426 tons; but in 1885 only 33,000 tons. But whilst the sales to the iron trade had decreased, the sales in the town had gone up. He was glad that trade in the iron-making districts had been increasing; and in 1887 the sales amounted to 51,141 tons. The complaint was made that the Birmingham consumers had to pay higher prices than outside customers; but the Committee were ruled by the consideration that the larger the quantity taken, the lower the price. The critics of the Committee said that the undertaking should be carried on for the benefit of the ratepayers; but he wished to remind such people that the works were conducted on economical principles, and for the purpose of securing the largest profit for the benefit of the ratepayers. The Committee had come to the conclusion that it was very unwise to stack coke, in consequence of the deterioration which ensued. It was found that if they put 100 tons down, they only took up about 20 tons of good coke. They therefore resolved to clear the yards every summer; and to do this they had had to sell at such prices as they could obtain. They had done all they could to promote the sale of coke in Birmingham; and the Birmingham people had had the coke at the market price. He

thought the feeling of the Committee was that they should have winter and summer prices. This year they would make £4000 to £5000 more out of the coke than in previous years.

Alderman BARRATT, in seconding the motion for the adoption of the report, asked if it was true that extraordinary advances of salary had recently been made by the Gas Committee—in one case as much as £250, in another £300—and as the result another application for £200 advance had been received; and if so how it was the Committee had not recorded this in the report submitted that day.

Mr. BISHOP, in reply, said it was true that such increases of salary had been granted. The reason why the matter was not brought before the Council was that from the time the Committee took over the undertaking no increases had been reported. When the Committee was appointed, an elaborate scheme was drawn up, upon which they acted, except in the case of their chief officers.

Alderman BARRATT thought it was time the Gas Committee mended its ways. He had been a member of the Corporation for many years, and must confess that he never heard of any Committee not reporting such matters. He would move—"That it be an instruction to the Gas Committee to report in future every increase of salary, in accordance with the custom of other Committees."

The MAYOR pointed out that Dr. Barratt rose to second the adoption of the report.

Alderman BARRATT: I will make the proposal at a future time.

Mr. CLARKE called attention to the quality of the gas. He said that he had made a number of tests, and found that the illuminating power of the gas averaged 13½ candles—the extremes being 12 and 17 candles. With regard to the point raised by Dr. Barratt, it did not follow that because a certain system had existed for several years, it was a good one.

The TOWN CLERK, in reply to a question, said there was no standing order that any Committee should report rises of salaries; but it had been the practice of all Committees to do so, with the exception of those controlling the Gas and Water Departments. These exceptions arose from the action of the Council itself. When the Corporation took over these undertakings, it was thought necessary to delegate to the Committees in charge of them "all the powers" of the Council, and that carried with it the power to appoint such officers and servants as were necessary.

Mr. LOWE moved an amendment—"That the report of the Committee be adopted; and that it be an instruction to the Committee to furnish to the next meeting of the Council full particulars of the recent increases of salaries of the officials of the Department; and further, that the Committee in future shall report to the Council all suggested increases of salaries in accordance with the custom and practices of other Committees."

The MAYOR: The latter part of the amendment is against the previous order of the Council; so that you must give notice of it.

Mr. LOWE said he would move the former part of the amendment only, and would give notice of the latter part.

Mr. BRINSLEY seconded the amendment, remarking that no doubt the resolution mentioned by the Town Clerk was carried; but in those days certain members had great power. The £250 increase was not the worst part of it; the Committee might have reported it to the Council afterwards. He quite agreed that large salaries must be paid for head officials; and no Corporation was better officered than that of Birmingham.

Mr. JARVIS said this was an exposure of a system which was grossly irregular—"No, no."—and he held to that opinion in spite of what might be said to the contrary. Salaries had been added to a surprising extent; and he thought the ratepayers would feel that those who had not consulted the Council would deserve the strictest condemnation.

Mr. THOMASON hoped that the discussion would bring out a great many irregularities which he had complained of from time to time. The Council would do well to go a step further, and inquire into the appointment of officials, expenditure on deputations, and other matters. He considered that it would be well if these questions were referred to the General Purposes Committee.

Mr. LANCASTER inquired whether, in addition to the salaries paid to the engineers, any commission was paid upon any of their patents; also whether any of their patents were used in the Gas Department, and if so, what amount, if any, was paid for them. In regard to the subject of salaries, he thought that a man who was worth his money ought to be paid. Referring to the coke question, he asked how many tons of coke dust were taken away in canal boats last year? How was it they did not get more than one-half they ought to obtain from coke, which was the largest residual, and one which should pay the most?

Mr. CLAYTON pointed out that the Gas Committee had the control of two millions of capital; and whether they gave to two or three officials a hundred or two more for extra efficiency, it was of very little importance. It did not affect the rates; and considering the enormous amount of risk there was involved, they ought to get the very best officers. He hoped the Committee would not be "heckled" in its work by too great a reference of details to the Council itself. Until they had done something egregiously wrong, let them give the Committee their full confidence, and not trouble them by worrying them to come up for the approval of every small detail.

Mr. GRAMER remarked that he had not heard of anything the Committee had done which had excited so much indignation as this advance of salaries. They might be certain that the matter would be brought forward again, and that a motion would be made in October for the reduction of the salaries to their former amounts. Many members, moreover, were of opinion that Mr. Hunt alone would manage the two concerns much more efficiently. The Engineers would both run away together to The Gas Institute—neglecting their work, and dragging the name of Birmingham through the mire at the same time.

Mr. BLOOR asked whether it was in accordance with the common practice of the Corporation to allow officials to trade outside the Corporation, or to pay commission or royalties to them.

The MAYOR said that no Engineer or employé of the Corporation had a right to exact a commission from the Corporation. No such commission or royalty had ever been or could be paid.

Alderman COOK did not wish to dispute the great powers given to the Committee; but it seemed to him the very reason why they should make the Council their confidants. In his opinion, they ought to have reported immediately after making these large advances. Alderman BARRATT had done a public service in raising the question; for it was a matter of common talk outside. He did not think that the justness of the advances would have been disputed, for he believed that they had been well deserved; but that was the very reason why the Council should have been told of them.

Mr. BISHOP said that he would accept the amendment. The Committee had had no indisposition to report these things. The Council had not asked for a report before; but the Committee would be very happy to give such reports in future.

Mr. WHATELEY asked Mr. Bishop to give them some reason for increasing the salaries, so that they could in turn afford the information to their constituents.

Mr. BISHOP observed that the salaries had been increased because of the

good work which those who received the increases had done. Some gentlemen said that they had never heard of a secretary of a gas undertaking receiving so much as Mr. Smith; but some of the London secretaries received a very much larger sum. In "Field's Analysis" they would find that Birmingham stood almost at the lowest point in the matter of salaries when the amount of gas was taken into consideration. If they added to salaries other matters, they would find that Birmingham was at the lowest point when compared with other towns in the kingdom. With reference to the tests of the gas spoken of by Mr. Clarke, the Committee's results were diametrically opposed to those given by that gentleman. At the same time that he found an illuminating power of 13 candles, the Committee's test gave 17 candles.

The report was then approved, and the resolution carried.

A meeting of the Gas Committee was held last Thursday morning to consider the question of the workmen's holidays, in accordance with the resolution passed by the Town Council. Subsequently the Mayor and the Chairman of the Committee (Mr. Bishop) communicated the result of the meeting to the representatives of the various newspapers. The Mayor explained the action of the Committee hitherto upon the question; commencing with the decision last year not to employ the men on Sundays except on urgent occasions. The promise of extra remuneration for Sunday labour was of little avail to the men, and therefore the Committee announced that they intended to give the stokers and carbonizers a holiday during the summer months. The matter was debated in the Council; and it being resolved that the men should be paid 1½ days' pay for Sunday work, the Committee's proposal fell through. After reading extracts from the newspapers in reference to the vote, the Mayor went on to say that immediately afterwards the stokers at Adderley Street and Swan Village memorialized the Council in favour of holidays instead of extra Sunday pay, but as the Council had in the previous year negatived indirectly the Committee's proposal, they thought it advisable to refer the matter to the General Purposes Committee to lay down a general principle applicable to all departments of the Corporation. At the last meeting of the Council the matter was referred back to the Committee, and they therefore passed the following resolutions at the meeting that morning:—"Resolved, that a holiday of one week (equal to 6½ days) in each year be given during the summer months to the firemen, stokers, machine men, coke wheelers, and odd men—such men being described as carbonizers, or men working in the retort-houses—who have been employed not less than ten months in the year ending June 30; it being understood that such holiday is to be an actual holiday, or rest from work, and that no money compensation is to be paid in lieu thereof."—"Resolved, that a holiday on Christmas Day, Whit Monday, and the first Monday in August, or other days in lieu thereof, be granted to all workmen who have been for not less than ten months in the year ending June 30 in the direct employment of the department, other than the carbonizers, who have been dealt with in the previous resolution; it being understood that such holiday is to be an actual holiday or rest from work, and that no money compensation is to be paid in lieu thereof."

EDINBURGH AND LEITH GAS COMMISSIONION.

A Meeting of the Edinburgh and Leith Gas Commissioners was held last Tuesday—Bailie TURNBULL presiding.

A conversation arose regarding the appointment of Mr. J. M. Jack as interim Clerk; the qualifying word being objected to by the Parliamentary Agent. To avoid complication, it was agreed to state in the minutes that Mr. Jack was appointed Clerk during the pleasure of the Commissioners; the appointment being in the meantime for three months.

The minutes of several Committees were read. One of them stated that the Committee appointed on the 27th ult. to confer with the Committee of the Directors of the Edinburgh Gaslight Company as to the arrangements for the transfer of the Company's undertaking, met in the premises in Waterloo Place on the afternoon of the 30th. The Company's Committee made the following suggestions for the consideration of the Commissioners:—(1) That Mr. Watson, on behalf of the Company, should be allowed, by himself and an assistant, to occupy his present room until the Company's affairs were wound up; (2) that a statement should be made by the Company and submitted to the Commissioners of the accounting between the Company and the Commissioners, and that this statement and all questions connected with the accounting should be submitted to Mr. J. A. Molleson, C.A., as sole arbiter; (3) that Mr. George Livesey, C.E., should be appointed sole valuator and arbitrator under section 20 of the Act; (4) that the Company's present collectors should, at the Company's expense, collect the accounts for the spring quarter due to the Company; (5) that the proportion of the current quarter's accounts for gas due to the Company should be calculated from an average date, so as to determine in a fair and equitable manner the amount due to the Company up to the 1st of August, and which should be collected by the Commissioners at the same time as they might make their first collection—the Commissioners paying to the Company its proportion, less a commission of 10 per cent.

A meeting of the Works Committee was also held on the 31st of July with the Edinburgh and Leith Gaslight Company. After discussion the parties agreed to recommend as follows:—(1) That Mr. George Livesey, C.E., should be appointed sole valuator and arbiter under section 20 of the Act; (2) that Mr. Livesey shall determine the proportion of gas-rental due to the Company as at the 1st of August 1888, and the terms upon which the rental shall be calculated and paid by the Commissioners to the Company; (3) that Mr. Linton shall at twelve o'clock to-night note the quantities and kinds of coal, coke, lime, waste lime, and stock of gas within the gasholders and pipes; (4) that Mr. Linton and Mr. Gibb shall, until other arrangements be made, continue in the service of the Commissioners at the salaries they are presently receiving from the Company—Mr. Linton as Engineer and Manager of the Leith works, and Mr. Gibb as Treasurer at the Edinburgh office.

Bailie ARCHIBALD explained that the two Companies took different methods of determining the quantity of gas due to them at the 1st of August. The Edinburgh Company began a survey of all their meters on the 19th of July; and they would calculate on the quantities eleven days before and eleven days after the 1st of the month. The Edinburgh Company wanted the Commissioners to take over their bad debts; but the Commissioners did not wish to prosecute people for money which the Company had not been able themselves to collect. The Leith people, on the other hand, did not take the accounts of any meters at all. The register at midnight on the 1st of August was taken; and the Commissioners had agreed to allow Mr. Livesey to determine what was the amount due to the Leith Company, as at the 1st of August, and the terms upon which this was to be paid for.

The CLERK stated that, as the Leith Company's inventory appeared to contain a number of articles, in the shape of tools and material which did not, in the opinion of the Committee, come into the category of "stores" under the 20th section of the Act, he was instructed to make a

preliminary objection on this point to the arbiter, and to ask him to exclude from the valuation every article which had been used, and was being used. The same would apply to the inventory of the Edinburgh Company. He was also instructed to ask Mr. Beveridge, the Parliamentary Agent, to make objection on this point.

Mr. COLSTON having quoted from the Act, Bailie ARCHIBALD said the real question was, whether implements such as barrows, shovels, &c., which had been used as "stores," were within the category. The Committee said they were not; and therefore they had advised that an objection should be taken before the arbiter on the point at issue. If it was argued that barrows, shovels, picks, and tools required by the men were included, they might take in the meters and pipes also.

The minutes were adopted. The Finance Committee reported that £10,000 of the mortgage debt of the Leith Company fell due at Martinmas. By the 11th inst. they would require to give notice whether they would renew these loans, or whether they would pay them off. The loans were at 4 per cent. The Committee recommended the Commissioners to renew the loans, for five or seven years, at 3½ per cent. The Finance Committee further recommended that at the next meeting they should appoint a Treasurer and collector.

The recommendation was adopted.

GLASGOW CORPORATION GAS SUPPLY. ANNUAL REPORT.

The Glasgow Corporation Gas Committee have within the past few days completed and passed their nineteenth annual report and financial statement, which applies to the year from June 1st, 1887, to May 31st, 1888. It will this week be issued to the members of the Town Council generally; but as August is a "holiday" month with them, it will not formally be brought forward for final approval till the meeting of the Gas Trust in September. There is every probability, however, that all the recommendations made by the Committee will be accepted without any material modification. A number of the facts dealt with in the report have from time to time been incidentally mentioned in the JOURNAL; but it may be convenient here to give a full summary of the report as prepared by the Gas Committee.

In that portion of the report which deals with finance, it is stated that

The gross revenue amounts to	£383,566	3	7
The gross expenditure to	£285,125	10	8
To this is added depreciation written off capital	49,379	8	9
Interest on borrowed money (including £7414 19s. 1d. of interest on redeemed mortgages paid into sinking fund)	2,000	0	0
Sinking fund	2,000	0	0
	381,191	14	9
Leaving a surplus on the year's operations of	£2,374	8	10
To this falls to be added the balance at the credit of profit and loss account carried from the previous year's account	2,826	13	4

Makes a sum to be carried forward to next year's accounts of £5,201 2 2

This summary of the financial arrangements which have commended themselves to the Gas Committee does not seem to indicate much prospect of the proposal which Bailie Shearer has before the Gas Trust, which is to take a sum of £5000 from the year's profits to be devoted to the purposes of the "common good" of the city, or for carrying out public improvements. It would almost appear as if the members of the Gas Committee had determined that the balance to be carried forward should be reduced to such an amount (by writing off for depreciation, &c.) as to leave little or no encouragement for that gentleman to proceed with his motion when the accounts come up for consideration.

The Committee state that they advertised for tenders for coals to be supplied during the current year, and that they have bought the greater portion of the quantity required on terms equally favourable with those of last year. On this account chiefly, they have agreed to recommend that a reduction be made in the price of gas from 2s. 10d. to 2s. 8d. per 1000 cubic feet; this reduction to take effect retrospectively as from the date of the last meter-survey. The probability of a reduction being made in the price of gas to the extent of 2d. per 1000 feet was mentioned in the JOURNAL a fortnight ago.

During the past year the amount of gas sold or accounted for was 2,427,078,000 cubic feet; being an increase of 6·21 per cent. over that of the year 1886-7, when it was 2,285,136,000 cubic feet. The quantity of gas made during the year was 2,705,440,000 cubic feet, as against a make of 2,596,470,000 cubic feet in the preceding year. The report states that the sinking fund now amounts to £204,518 0s. 3d.

Under the head of "Works" the report informs us that the exhaustor machinery mentioned in the preceding report in connection with the Dalmarnock works was completed and put in operation during last winter. All the apparatus at these works has been kept in thorough repair. Additional ground has been purchased, and will be utilized in the future development of these works. As regards the Dawsholm works the Gas Committee state that the new scrubbers and station meters mentioned in the report for 1886-7 were completed in time to be put in operation last winter. No further extensions have been made at these works; but the apparatus has all been kept in thorough repair. As anticipated in the preceding report, a scheme for the reconstruction of Tradeston works was submitted to, and approved of by the Town Council; and an Act was obtained in the present session of Parliament authorizing the extension of the works proposed in the scheme. Plans are now being prepared; and estimates will shortly be submitted for the bridges and other preliminary works, and the reconstruction contemplated will be commenced as soon as possible after next mid-winter.

During the past year the loss by unaccounted-for gas amounted to 10·29 per cent., which is less than that of any previous year. As compared with that of the year 1886-7 it shows a decrease of 1·7 per cent. In the year 1885-86, it was 11·32 per cent.; and in the preceding year it was 10·66 per cent. If we mistake not, the last-mentioned result was obtained in the year after the service-pipes and street mains had undergone a thorough overhaul.

The greatest quantity of gas consumed in a period of 24 hours during the year 1887-8 was 16,287,000 cubic feet, as compared with 16,266,000 feet in the preceding year. At the end of the past financial year, the number of meters in use was 130,237; being a decrease of 362 as compared with the total in use at the same time in 1887. During the year 18,603 meters were repaired at the Walls Street workshops; and in the course of the year 14,768 were examined while in use, and found to be in a satisfactory condition, and 2202 were found defective and removed. New mains of a

total length of 13,901 yards (or well-nigh eight miles) were laid during the year. As regards the hiring and sales of stoves and other gas appliances, satisfactory progress continued to be made during the past year. The hires included 1465 stoves, &c.; and the gas heating and cooking appliances sold during the year amounted to 1193.

Some more detailed reference may now be made to the various accounts embraced in the financial statement. The stock capital created in the shape of "Glasgow Corporation Gas Annuities," when the works and interests of the Glasgow Gaslight Company and the Glasgow and Suburban Gas Company were taken over by the Corporation in the year 1866, was £300,000, bearing perpetual annuities at the rate of 9 per cent. per annum, and £115,000 rated at 6½ per cent. per annum. Collectively, the yearly annuities or dividends amount to £34,762 10s. The loan capital authorized is £1,000,000; but only £287,345 has actually been borrowed—leaving the sum of £712,565 as still available. The major portion of what has been borrowed—£188,435—consists of mortgages redeemed out of the sinking fund, which is composed of revenue set apart to be used in the redemption of mortgages and annuities. It is provided in the Corporation Gas Act that to what extent mortgages are redeemed out of it, to the same extent the borrowing powers of the Gas Trust shall be cancelled. The Act further provides that interest shall accrue to the sinking fund on the mortgages so redeemed, which is also to be applied in the same way.

In the statement dealing with the capital account, it is shown that the Dalmarnock station and works and the Dawsholm station and works are now valued, respectively, at £96,501 14s. and £141,536 7s. 6d.; the amount written off for depreciation during the year being in each case 5 per cent. The same percentage has also been written off the value of the Tradeston station and works, which are now rated at £51,910 15s. 2d.; but in addition the sum of £12,000 has been written off as an "extra" for the purpose of meeting renewals, so that they will now actually stand in the books at the value of £39,910 15s. 2d. In the statement of accounts issued at this time last year, the amount written off for depreciation was in each case 7½ per cent., which is the rate for depreciation written off at this time in making valuations of several other large items of property. The workshops in Walls and Stirling Streets, with depreciation and additions during the past year, are now rated at £10,931 13s. 3d.; and the Chemical works at Dawsholm are valued at £7911 8s. 7d. With extensions made during the year and the high rate of depreciation, the pipes and cost of laying are put down as being valued at £178,732 6s. 4d. As regards the gas-meters belonging to the Gas Trust, depreciation has been made at the rate of 6 per cent.; and with additions during the year amounting to £8097 15s. 10d., the total value is now set down at £108,579 5s. 3d. The net value of the gas-stoves, &c., on hire and in stock is given at £11,833 7s. 6d. When these various items and those referring to property in Partick, offices in Virginia Street, workmen's dwelling-houses at Dawsholm, counting-house furniture, &c., are taken into account, together with a balance of £91,165 0s. 7d., there is a grand total of £702,435.

Coming to the statement under the head of Revenue account, we find that 276,447 tons 6 cwt. of coal were used last year, the cost of which (with carriage) was £143,273 12s. 7d. Including the cost of purifying materials, &c., the salaries of engineers, superintendents, and officers at works, workmen's wages, repairs and maintenance of works and plant, machines, apparatus, tools, materials and labour, and carting and stabling account, there was a total expenditure for manufacture of gas amounting to £227,082 11s. 6d. In like manner, the distribution of gas involved an outlay of £32,227 12s. 8d. The rents and feu duties, rates, assessments, and taxes are set down at £16,147 6s. 6d. For salaries and other expenses connected with the management in the Treasurer's department in Virginia Street, there is a total of £7975 15s. 6d. Law and Parliamentary charges are set down at £1275; and the retiring allowances to old servants of the Gas Companies at £417 4s. 6d. With the sum of £49,379 8s. 9d. written off for depreciation of works, pipes, meters, etc., the grand total is £334,504 19s. 5d. For sales of gas, and including a sum of £4442 16s. of arrears of previous years recovered over the estimate, there was obtained the sum of £338,498 7s. 6d. The coke sold realized £16,105 16s. 7d.; and the income from ammoniacal liquor and tar was £26,637 7s. 10d.—or together the residual products yielded £42,743 4s. 5d. For waste lime a sum of £972 9s. 10d. was obtained. These and several other items made up a revenue of £383,566 3s. 7d.; so that there was a balance of £49,061 4s. 2d. to carry to profit and loss account.

Under the head of profit and loss account (net revenue), we find the annuities on stocks for the year ending Whitsunday, 1888, set down at £33,748 11s. 10d., after deducting £1013 18s. 2d. in the shape of income-tax. Then we have interest on mortgages, and redeemed mortgages, &c., for the same year, amounting to £10,988 3s. 6d. The sum carried to sinking fund, as already mentioned, was £2000. These items, together with the balance of £5201 2s. 2d. carried to next year's account, make up a total of £51,887 17s. 6d., which is exactly the amount of last year's balance brought forward and that of £49,061 4s. 2d. just referred to as having been brought from revenue account, and which is profits.

The general balance-sheet shows on the one side a balance of £91,165 0s. 7d. at the credit of capital account; a balance of £5201 2s. 2d. at credit of profit and loss account; a sum of £14,766 6s. 5d. in the shape of deposits in security of gas-rents, &c.; a benevolent fund amounting to £3272 13s. 11d.; accounts due to sundry tradesmen and others for coal, &c., amounting to £12,193 1s. 6d.; sinking fund, £204,518 0s. 3d.; and a small item in the shape of unpaid annuities. All these give a total of £331,143 19s. 5d., which sum also appears on the other side of the balance-sheet, and includes various outstanding revenue assets, £56,233 4s. 2d.; stocks on hand, horses at stables, &c., £20,586 15s. 11d.; sinking fund, £202,518 0s. 3d.; temporary loan of £30,000 to Corporation of Glasgow; balance in bank, £21,294 17s. 9d.; outstanding accounts for stair fittings, gas-stoves and fittings, and hires, &c.

CORK GAS CONSUMERS' COMPANY.—The Directors of this Company, in the report to be presented to the shareholders at their meeting to-day (which bears the signature of the Secretary, Mr. Denny Lane), state that the accounts to the 30th of June last show a satisfactory and steady business, without any remarkable features. There was a small increase of £142 in the rental from private consumers; while the revenue from public lighting decreased by £44—leaving a net increase of income of about £100 for the six months. The Directors have added £350 to the depreciation fund, and after this allocation the balance of profit and loss amounts to £5720 13s. 8d. Out of this it is proposed to pay the usual dividend at the rate of 8 per cent., which will require about £5688, and leave about £32 to be added to the reserve, which will then stand at £11,911. The Directors' report is accompanied by that of the Company's Consulting Engineer (Mr. G. Anderson), who states that, with the exception of the painting of the external ironwork, which has been delayed in consequence of the very bad weather, the works are in good condition. He considers that the manufacturing operations have been economically conducted; a larger return having been received for residuals than is usual on other works.

ABERDEEN CORPORATION GAS SUPPLY.

THE ALLEGED INCREASE OF GAS ACCOUNTS.

In his recent communications, our Edinburgh Correspondent has referred to the agitation by gas consumers in Aberdeen over the alleged increase of their accounts, notwithstanding the reduced price charged for gas. The result of a deputation of consumers to the Town Council on the subject, it may be remembered, was a promise on the part of the latter body to inquire into the matter; and they accordingly appointed Dr. Wallace, of Glasgow, to report upon the coal used for the manufacture of gas during the year ending May last, and also on the coal purchased for next season, and the City Chamberlain (Mr. Cran) and the Gas Manager (Mr. A. Smith) were instructed to examine the books, and to prepare a statement setting forth the amount of the gas accounts of householders in different streets for the last and the preceding two half years.

A meeting of the Gas Committee was held on the 2nd inst., when the report by Dr. Wallace, to which reference was made by our Edinburgh Correspondent last week, was brought forward. A report on the subject was also tabled by the Gas Treasurer.

Dr. Wallace, in his report, stated that he had found that the average of 32,000 tons of coal, including fourteen varieties, for the year ending May 15, 1888, taking the respective quantities of the coal into account, should give, according to the published analyses of the coals, 10,775 cubic feet per ton, and an illuminating power of 27.60 candles; and the average of 33,000 tons of coal, including fifteen varieties, for the year ending May 15, 1888-9, 11,078 cubic feet, and 27.31 candles—the durability being 57 min. 40 sec. and 57 min. 44 sec. respectively. These figures showed that the coal for the two years, though not identical, were very much alike; and the quantity of gas to be slightly greater for the latter year, but the illuminating power rather less. The durability of the gas was practically identical. The quantity of gas actually obtained per ton of coal during the year ended May, 1888, was stated to be 10,253 cubic feet; and as there was an almost exact relation between the quantity and quality of gas, at least within reasonable limits, the quality of gas during the past year should have been exactly 29 candles. If the same heats and modes of working were adopted during the present year, the quantity of gas per ton of coal would probably be about 10,524 cubic feet, and the illuminating power 28.75 candles. The coals selected for the present year gave a large yield of gas of excellent quality. In Glasgow the illuminating power had been reduced from 26½ to 23 candles; and it was an absolute fact that, since the reduction took place, there had been a marked diminution of complaints as to the quality of the gas supplied by the Corporation. What was wanted, therefore, for the satisfactory supply of a city or town was not so much a high quality of gas as a sufficient supply at all times from the works, and a constant supervision of the different districts, to see that the mains were of a size requisite to give the necessary pressure at the point of ignition. A high illuminating power was not good for either heating, cooking, or motive power; and a fair compromise in the case of the city of Aberdeen would be an illuminating power of 25 candles, and this Dr. Wallace was of opinion would give satisfaction to all parties. Referring to the pressure at the burners, the report states that it should be about 9.10ths. If the pressure at the point of ignition exceeded 11.10ths or thereabouts, there was a decided loss of illuminating power in proportion to the quantity of gas consumed. With regard to the quantity and quality of gas obtainable from the various coals, it was scarcely to be expected that in regular working results equal to those obtained in special trials should be obtained; and a discount of 5 per cent. from the number of pounds of sperm per ton of coal would be a reasonable allowance. That was to say, if, during the year just ended, the gas produced was 10,253 cubic feet per ton, the illuminating power should have been not less than 27.5 candles.

The report by the Gas Treasurer showed the amounts of the accounts of consumers for the three years ending May last in Causewayend, Market Street, Ferryhill Place, Watson Street, and Frederick Street. It stated that in Causewayend, 59 accounts had increased and 56 decreased; in Market Street, 34 had increased and 19 decreased; in Ferryhill Place, 17 had increased and 7 decreased; in Watson Street, 62 had increased and 38 decreased; and in Frederick Street, 40 had increased and 22 decreased. The increase in 1887-8 of gas consumed over 1886-7 was 2.33 per cent.; the decrease in 1887-8 on the amount paid in 1886-7 was 2.01 per cent.

The Committee deferred consideration of Dr. Wallace's report until the specific statement as to increases in the gas accounts had been received.

GAS PROFITS OF THE BURY CORPORATION.

The much-disputed question as to the form which the accounts of the Bury Corporation Gas Department should assume seems to be now in a fair way for settlement. The point, which was debated at length at several Council meetings held in the summer and autumn of last year, was whether the Gas Committee were not making out their balance-sheet in such form as to result in a double payment of income-tax on a moiety of the actual profit realized each year. To some extent the difference of opinion arose out of the interpretation put upon a section of the Local Gas Act, which directs that the profit is to be equally divided between the consumer and the ratepayer—the former to receive his share in a "reduction of the price of gas for the then next ensuing year." The contention of the Finance Committee was that, in carrying out this arrangement, the accounts were so manipulated that the same profit was taken credit for in two successive years, and was thus subjected to double taxation. Although the Gas Committee opposed this view very strongly, the local Income-Tax Commissioners upheld it; and the result was that a deduction was made from the last year's accounts for the sums brought forward from the profit of the previous year. An appeal was threatened to the Commissioners of Inland Revenue, against the decision of the local Commissioners; and the Finance Committee seem at the same time to have given notice of a claim for the return of the excess of taxation paid as they alleged in previous years. The following letter from the Inland Revenue Office, dated the 25th of July, appears, however, to promise a settlement of the whole matter:—"With reference to the letter of the 9th of May last, on the subject of the additional income-tax assessment on the Corporation of Bury, for the year 1886-7, in respect of gas profits, I am directed by the Board of Inland Revenue to acquaint you that the case demanded by their Surveyor on the appeal of the Corporation will not be proceeded with on the understanding that, as stated in your letter, the Corporation withdraw their claim to return of duty for former years." The letter was entered on the minutes of the Finance Committee which were adopted at the last Council meeting; and as there was no comment upon it, it may be assumed that the accounts will be so presented in future as not to admit of the possibility of the question being re-opened.

The Newcastle and Gateshead Gas Company have declared an interim dividend of 4½ per cent. for the past half year. Some further works extensions are contemplated.

The Wardle Local Board decided last Thursday not to entertain the terms submitted by the Public Lighting Company for the lighting of the district with oil instead of gas.

WARRINGTON CORPORATION GAS SUPPLY.

BOROUGH TREASURER'S ANNUAL REPORT.

The Annual Report of the Borough Treasurer of Warrington, lately issued, furnishes some information as to the result of the working of the gas undertaking during the year ended the 25th of March last. The receipts on cash account amounted to a total of £65,640 14s. 3½d.; the items being as follows:—Sales of gas and meter-rents, £26,500 10s. 1½d.; fittings, £936 19s. 3d.; coke, £2260 17s. 7d.; tar, £750 4s. 10½d.; sulphate of ammonia, £2457 11s. 6d.; purifying materials, £216 5s. 5d.; sundries, £251 15s. 6½d.; cottage-rents, £288 0s. 10d.; rent of stoves, £49 14s. 11d.; deposit on tar contract, £300; consumers' deposits, less amounts repaid, £158 6s. 4½d.; bankers' cash and sundries, £31,635 3s. 11d. On the expenditure side the items are as follows:—Wages for gas manufacture, £2550 14s. 2d.; repairs, £1490 9s. 2d.; coal and cannel, £10,385 10s. 9d.; purifying, £302 6s. 4d.; water, £260 3s. 7d.; retorts and fire-bricks, £553 4s. 1d.; meter inspection and repairs, £632 17s. 8d.; lamp repairs, £143 5s. 7d.; lamp lighting, £525 18s. 1d.; salaries, £1246 13s.; rates and taxes, £1598 8s. 2d.; office expenses, £99 19s. 6d.; fittings, £782 11s. 10d.; cottage repairs, £35 10s. 10d.; rates on cottages, £41 16s. 9d.; law expenses, £2 8s. 2d.; interest on deposit account, £2 16s. 6d.; interest on deposit on tar contract, £6; sulphate of ammonia, £500 12s.; capital expenditure, £32 14s. 9d.; general expenses, £145 4s. 2d.; sundry payments to bankers, £33,964 11s. 7d.; payments to Borough Treasurer, £10,008 1s.; cash in hand, £11 1s. 7½d.

Mr. James Paterson, F.G.S., the former Gas Engineer of the Corporation, has furnished the following statement respecting the work of the department during the year and its predecessor:—

	Year ended March 25.	
	1888.	1887.
Coal and cannel carbonized	22,224 tons.	20,558 tons.
Gas made	214,000,100 c.ft.	200,933,700 c.ft.
Do. per ton of coal carbonized	9,621 "	9,632 "
Do. sold per meters and accounted for	180,147,150 "	172,845,430 "
Gas distributed per mile of main	5,132,500 "	5,021,460 "
Do. rental per 1000 cubic feet of gas made	2s. 10.63d.	2s. 11d.
Do. do. received for every 1000 cubic feet sold	3s. 5.00d.	3s. 5.00d.
Do. do. per mile of main	£774 4 0	£627 14 0
Capital employed in works and plant	£175,126 2 0	£178,181 14 10
Do. do. per ton of coal carbonized	7 17 6	8 11 9½
Do. do. per million cubic feet of gas made	818 7 0	886 9 6
Do. do. for every £100 of gas-rental	567 0 11	602 1 3
Gas-rental for every £100 expended in capital	17 12 8	16 11 3
Do. do. for every £100 expended in coal and cannel	284 8 0	294 16 0

THE MANAGEMENT OF THE GAS-WORKS.—VOTE OF CONFIDENCE IN THE GAS COMMITTEE.

At the Meeting of the Warrington Town Council last Tuesday—the Mayor (Alderman Sutton) presiding—the Gas Committee reported that eight of their number, including the Chairman, had resigned, in consequence of the adverse vote of the Council at the previous meeting, on the proposition to appoint Mr. J. Paterson, F.G.S., the retiring Engineer and Manager of the works, as Consulting Engineer to the Gas Committee.

Alderman HOLMES, in proposing that the minutes be confirmed, referred specially to the resignation of himself and other members. Alluding to what took place at the previous meeting, he said an amendment was proposed to the Committee's recommendation, asking them to withdraw the resolution which they had proposed, and bring in another, recommending that the allowance to Mr. Paterson should be continued for only twelve months. It was utterly impossible for the Committee, having considered the question so closely, to bring forward a fresh scheme. They had told the Council very emphatically that the scheme they proposed was what they deemed to be the best, in the interests of the Committee, and of the ratepayers at large. They, therefore, considered that there was no other course open to them than to place themselves before the Council, to give them a chance, if they saw cause, to accept their resignations; or if they did not feel inclined to do so, then the Committee would see that they had, as they believed they ought to have, the confidence of the Corporation. They were not at all adverse to fair criticism, but they thought they should have a fair amount of confidence reposed in them, or else the life of the Committee would not be worth having. If the Council chose to accept their resignations, well and good; but if, on the other hand, they chose to retain their confidence in the Committee, the latter would continue to work in the interests and for the welfare of the town, as they had endeavoured to do in the past.

Alderman DAVIES, who said his motive was to lift the blind which was upon the eyes of the people of Warrington as to the advantages which the purchase of the gas-works conferred upon the town, went at some length into the history of the undertaking. He said that when the Corporation bought the works, the total quantity of gas made was 119,008,500 cubic feet, of which 102,005,206 cubic feet were sold; showing a leakage of 17,003,294 cubic feet, or 14.8 per cent. So that the management of the works well under the control of the Committee had not shown any depreciation whatever. The leakage mentioned included the loss on the public lamps—that was, the difference between the quantity of gas charged for and that actually consumed. This had remained to the present day; and there had absolutely been a loss to the Committee on the charge for the lighting of the lamps in the borough. In a report published at the time the works were purchased, he read: "We may here observe that the Company's properties and effects are in first-class order and condition; indeed, we have learnt that the plant has been almost entirely renewed during the last twelve years." This statement upset the theory that they were buying old and dilapidated works. The next thing was that they not only bought an undertaking which was producing £6661 a year, but they bought a concern which had a balance of £10,600 to its credit. He admitted that it was effected by a loan of £5000, and likewise by a sum of £2700 which they paid in cash; but the fact remained that there was a surplus of £6600, for which they gave £6120, leaving a margin of about £500 in the interests of the borough. The Committee who drew up the report from which he had quoted, estimated that the investment would end in a profit of £7128 to the Corporation. Had this hope been realized? At the end of last year, after the annuities and sinking fund (which amounted to £10,008) had been paid, the surplus was not £7128, but £15,319. In addition to this, they had reduced the price of gas no less than 6d. per 1000 cubic feet—that was,

6d. per 1000 feet less than perhaps it would have been had the Company still owned the works.

Mr. MONKS: You cannot tell that.

Alderman DAVIES admitted that he could not; but he thought the Committee were entitled to take credit for what they had done. He could well understand that the Committee had been very much annoyed and grieved at the action of the outside public, who had contributed letters to newspapers. These letters and the action of the people to whom he had referred had done a great amount of injury; for they appealed to the unthinking portion of the public, and put them against those who were trying to do good to the town. Taking everything into consideration, he thought the Council would be perfectly justified in passing an amendment declining to accept the resignations, and stating that the Council have unabated and unreserved confidence in the Committee, with the earnest request that all the members will continue to give their valuable services as heretofore for the benefit of the Corporation, town, and neighbourhood. He proposed an amendment to this effect.

Mr. PLATT seconded the amendment, and expressed his belief that if they were to go through Warrington they could not pick out ten better men than those now on the Committee. In moving his amendment on the previous occasion, he had no intention of expressing any want of confidence in the Committee.

Alderman CROSFIELD said Alderman Holmes had been one of the most valuable servants of the Corporation for the last 30 years; and it would be base ingratitude on the part of the Council if they did not respect him.

Alderman HARRISON said the action of the Council was not intended to lead the Gas Committee to suppose that confidence in them had been lost. He did not believe there was a Committee of the Council which took a more earnest or a more conscientious interest in the welfare of the town and in the duties entrusted to them than the members of the Gas Committee.

The Mayor said he was glad there had been such an expression of confidence in the present Committee, because it would be a great loss to the town to be deprived of the services of such experienced gentlemen as those whose names appeared in the minutes. Alderman Davies's amendment was then put and unanimously agreed to.

DARWEN CORPORATION GAS SUPPLY.

THE NEW GAS-WORKS.

The erection of the new gas-works at Shorey Bank, Darwen, which was authorized by the Darwen Corporation Act, 1887, is being briskly proceeded with; and it is expected that they will be in full working order by the beginning of the winter. The works are being built on the latest and most approved principle; and, in fact, every suggestion for the saving of time and money is being adopted. The whole of the work has been personally supervised by the Gas Engineer (Mr. T. Duxbury) and Mr. F. Arnott, of Leeds. Mr. T. Newbighing, C.E., of Manchester, has acted as Consulting Engineer for the Corporation throughout; and the result has been the production of a system of gas manufacture second to none in East Lancashire. The idea of new gas-works was mooted by the late Alderman Snape, who calculated that the outlay would bring in a profit of 5 per cent., whilst the money could be borrowed to carry out the work at 3½ per cent.; thus giving a clear saving of 1½ per cent. He counselled the Corporation to secure the power to do the work; and when the Darwen Corporation obtained their new Act last year, it was determined to proceed with it at once. The Act cost the Corporation £2878 18s. 9d. Excavating for the new works was commenced in June, 1887; and, judging from appearances, the works will be finished in about six weeks' time. They are built on a piece of land about 7 acres in extent, abutting on Robin Bank Road, and are separated from the old gas-works by the River Darwen. They are close to the railway line; and a siding has been constructed direct into the works. The first rail takes the coal into a large store, built on girders, over the top of one of the coal-stores. Here the coal will be weighed on a 20-ton weighing-machine which has been erected. Half the coal will be emptied into the store below; and the remainder taken on another elevated railroad outside the works, and shunted into a corresponding store on the opposite side of the building. Other waggons may be taken down an inclined plane into the lower store of the works, or on to the siding. The second or middle storey is divided into three portions. On each side are the coal-stores; and in the centre are the retorts. There are 28 furnaces, with seven retorts to each furnace, which are capable of producing about 1,372,000 cubic feet of gas in 24 hours. The retort-house is 182 feet long, 62 feet across, and 28 ft. 6 in. in height. The roof is ventilated; and there are two large chimneys springing from it to a height of 87 feet from the bottom storey on the Duckworth Street side of the building. The bottom is far below the level of Robin Bank Road, and will be used at present solely for storage purposes. It has been erected, of course, to allow of the ready adoption of a regenerative system of firing. Space is also left on each side of the retort-benches, in order to allow of the use of mechanical stokers. The building throughout is of plain brick, with stone dressings. The foundations are all of stone; and the walls vary in thickness from 2 ft. 9 in. to 2 ft. 4½ in. The floor of the retort-house is covered with thick cast-iron plates. Extending from the main building on the Frederick Street side is a small structure of rather less elevation, two storeys in height. Railway waggons can be run into the top storey from the coal-store near to the railway; and waggons of oxide of iron, lime, and other materials for the old gas-works will be conveyed there. Two tips will be provided; so that the Corporation carts can be taken into the room below and readily loaded. They will then cart the goods to the old gas-works; and by this means a large amount of loading will be saved. At the top of the works are large tanks for water and gas tar. The tar will be pumped by steam power from both works into the tanks; and afterwards, by opening a valve, will be poured into the boiler waggons in the sidings below. Here another saving of cartage will be effected, as in the past the tar had to be conveyed from the works to the station by horse power. After the gas has been manufactured, it will be taken by means of pipes to the old works, where the washing, scrubbing, and general purification will still be carried on. There is an extensive vacant space between the new works and the River Darwen. A large portion of this will be paved, and used for the storage of pipes and other requisites. The river is to be covered with iron girders and arched over; and this again will provide a capital storage place. There will be a very large quantity of pipes from one works to the other. They will include a duplicate set of 20-inch mains to convey the gas to the purifiers, tar-pipes, acid-pipes, and steam and water pipes. These are to be carried across the river on a trestle-girder bridge, which is now being built, and has a clear span of 70 feet; and there will also be another bridge for the passage of carts containing oxide of iron, lime, &c. This bridge will have a span of about 20 feet, and will be about 20 feet wide. In the old gas-works a number of alterations are also being made; and sulphate plant is being put down. Altogether, the gas-works, when completed, will doubtless be a source of great saving to the town, and will justify the Corporation in their recent action of reducing the price of gas by 6d. per 1000 cubic feet.

RECENT SALES OF SHARES.

At a sale of shares in the *Scarborough and Malton Gas Companies*, held by Messrs. Botterell and Son at Malton last Tuesday, some unprecedentedly high prices were realized. The first parcel submitted for competition consisted of 35 original £10 shares in the Malton Gas Company. The first lot was knocked down for £25 5s. per £10 share; the second for £25 7s. 6d. per share; and the five succeeding lots, at £25 10s. per share. The shares all went to one purchaser, who also gave £165 for a lot of £90 stock in the Scarborough Gas Company, and £8 15s. for a £4 lot. On the following day, Messrs. Renton and Renton, of Harrogate, sold by auction, at Knaresborough, a number of shares in the *Harrogate, Gainsborough, and Brigg Gas Companies*. A parcel of £160 of "A" stock in the first-named Company was disposed of at the rate of £325 per cent.; and £500 of "B" stock at £230, £235, and £237 per cent.; being an average of £233 8s. The 1887 dividend on the "A" stock was 14½ per cent.; on the "B" stock, 10½ per cent. A few fully-paid £10 shares in the Brigg Gas Company, Limited, on which 10 per cent. has been paid, were sold for £20 5s. each; some £3 shares in the same Company fetching £5 17s. 6d. each. Some original stock of the Gainsborough Gas Company was knocked down at the rate of £201 per cent.; three new £20 shares in the same Company (£12 paid) fetching £26 10s. each. With the exception of the last, the shares were all sold *cum div.* A further parcel of three £100 lots of "A" shares in the Harrogate Gas Company was afterwards submitted to competition, and realized £321 and £322 per cent. At the Mart, Tokenhouse Yard, on the same day, Messrs. Fox and Bousfield sold some £10 shares in the *West Kent Gas Company* (carrying a maximum dividend of 10 per cent.) at £19 15s. per share.

GAS-METER TESTING IN EDINBURGH.

We have been favoured by the Chief Inspector of the Edinburgh Gas-Meter Testing Department (Mr. G. F. Blackie) with certain statistics relating to the work of the department in the 27 years which have elapsed since its establishment. Taking the last twelve months (from Aug. 1, 1887, to July 31, 1888) first, we find that 13,022 new wet meters, 2903 repaired meters, and 123 consumers' meters were tested; making a total of 16,048. Of these 131 were incorrect, being 1 in every 122·504. Of dry meters there were 11,738 new meters, 5231 repaired meters, and 280 consumers' meters tested; making a total of 17,239. Of these 277 were incorrect, being 1 in every 62·234. The total number of meters tested during the year was 33,287, of which 408 were incorrect, or 1 in every 81·586. The amount of fees drawn was £1098 8s., being an average of 7·55d. per meter. There were 5418 less wet meters, and 2086 less dry meters tested in the year just closed, as compared with the preceding twelve months; and the fees paid were also less by £269 16s. 6d. The fees ranged from 6d. to 60s. There were 349 less wet meters, but 180 more dry meters repaired; making 169 less meters repaired in the year 1887-8. The following are the totals for the past 27 years:—Wet meters: Total number tested 667,359; incorrect, 2770—or 1 in 241·092. Dry meters: total number tested, 311,010; incorrect, 2342—or 1 in 132·797. Aggregate of meters tested: 978,669; incorrect, 5112—or 1 in 191·445. Total fees paid: £29,504 13s. 6d. or 7·24d. per meter; the fees ranging from 6d. to 150s. The first meter tested was on Sept. 16, 1861. The greatest number tested in one year was in 1887-8, when 47,833 passed through the department; the fees paid amounting to £1402, or at the rate of 7·03d. per meter. The least number was in 1873-4, when 29,085 meters were tested; the fees paid amounting to £878, or at the rate of 7·24d. per meter.

AN ELECTRIC LIGHTING SCHEME FOR CHELTENHAM.

At the Meeting of the Cheltenham Town Council last Tuesday, the principal business was to receive a report from the Electric Lighting Committee, which was appointed in November last, at the instance of Mr. G. Norman, who afterwards became the Chairman. The Committee have held many meetings, and have visited Taunton, Eastbourne, and other towns where electric lighting is in use. As the result of their investigation, they agreed upon the following report, which was laid before the Council:—"That, in the opinion of the Committee, it is desirable to try the experiment of lighting a portion of the town with the electric light. [The area was defined.] It is considered that 36 lamps, each of 1200-candle power, will suffice to efficiently light this area, and that about 170 gas-lamps will be thereby rendered unnecessary. Assuming that the lamps can be supplied, either by the Corporation itself or by contract, at the price of the tender accepted by the Bath Corporation for 70 similar lamps for a term of seven years—viz., £18 17s. 6d. per lamp, exclusive of the standards—the annual cost to the Corporation, exclusive of the standards or brackets, would be £679 10s. From this would have to be deducted the cost of the gas-lamps superseded, which at the present cost per lamp of £2 13s. 6d. would amount to £444 15s. per annum. That it be referred to the Committee to consider and report as to the best mode of carrying out the foregoing recommendation—whether by the Corporation itself or by contract. If the former alternative is considered preferable, to report as to the best means of carrying the works into effect; if the latter, to procure tenders." In moving the adoption of the report, Mr. G. Newman called attention to the plans prepared by the Surveyor (which were hung on the walls of the chamber), and promised that a more elaborate statement would be laid before the Council at a future meeting. It would then be in their power to accept or reject the scheme. Subject to this, the report was of an important character, as it asked the Council to say that the lighting of the streets by the electric light was desirable, if a proper scheme were submitted; to approve of the experimental area stated; and to give the Committee freedom of action in the carrying on of the lighting scheme, either by a private company or by the Corporation themselves. The experimental area included the principal streets of the town, and touched every ward. After dwelling at some length on the advantages of the electric light as a street illuminant, Mr. Norman expressed himself as strongly in favour of the Corporation undertaking the provision and supply of the light, in preference to entering into a contract with a private company, which might lead to the creation of a monopoly. The resolution approving the report of the Committee was agreed to; and it was referred to the Committee to report as to the best means of carrying out the scheme.

REDUCTIONS IN PRICE.—The *Richmond Gas Company* have given notice that the price of gas will, as from the 30th of June last, be reduced from 3s. to 2s. 10d. per 1000 cubic feet.—The *Kingston Gas Company* have informed the New Malden Local Board of their intention to reduce the price of gas 2s. per lamp as from Midsummer last.

ADOPTION OF OIL LIGHTING AT GRAVESEND.—At the meeting of the Gravesend Town Council last Wednesday, it was decided to substitute oil for gas in the lighting of the public thoroughfares, and the tender of a local firm to do the lighting with oil at the rate of 50s. per lamp, with a right to the Council to terminate the contract at one, two, or three years, was accepted. It was stated that this substitution would effect a saving of £250 per annum to the ratepayers.

ST. HELEN'S CORPORATION WATER SUPPLY.

THE NEW WORKS AT KIRKBY.

Reference was made in last week's JOURNAL to the laying of the foundation stone of the new pumping station at Kirkby, which work, when finished, will complete the water supply scheme which the St. Helen's Corporation have been carrying out during the past few years, under the powers of the Act obtained by them in 1882. A few particulars regarding the new works will be of interest; and these may be prefaced by saying that the St. Helen's water district extends over 12,000 acres, the population within which is estimated at about 68,000. It is computed that, when these additional works are completed, 5 million gallons of water per day will be yielded. In 1877 the average consumption of water was 2½ million gallons. The site at Kirkby is near to the main line of the Lancashire and Yorkshire Railway; and there is no public well nearer than Aughton (Ormskirk), which is four miles away. In the pebble beds of the new red sandstone formation, two wells similar to those at Knowsley have been sunk. Each well is about 11 feet in diameter, and 150 feet deep; being connected by a heading of 9 ft. by 6 ft., and a bore-hole 24 inches diameter, diminishing to 18 inches diameter, sunk from the bottom of one of the wells to a total depth of 510 feet from the surface of the ground. The Corporation have concluded negotiations for the supply and erection of a compound vertical rotary engine, two boilers, and other work connected therewith. At the completion of the sinking in September last year, it was estimated that the yield from the wells would be 1 million gallons per day, and from the bore-hole from 2½ to 3 million gallons in addition. The building, when finished, will measure 48 ft. by 48 ft.; and an octagonal castellated water-tower will rise to an altitude of 80 feet from the surface of the ground. In the tower, above the engines, there will be a travelling crane; and above that a compensation tank, which must always contain 30,000 gallons of water to meet the requirements of Lord Sefton's tenantry. The boiler-house will adjoin the tower. The engine foundations will go to a depth of 30 feet underground. The engines are expected to have a capacity equal to raising 1½ million gallons per day, or, on the assumption that each gallon of water weighs 10 lbs., no fewer than 15 million pounds. When the Kirkby works are ended, the Corporation will have at their disposal pumping power capable of delivering about 4½ million gallons of water per day; and according to estimate, there are in addition to this from 2 to 2½ million gallons available in the Kirkby wells if required. The parliamentary estimate for the carrying out of the whole of the works was £95,000; and the Water Committee believe that they will be able to complete the scheme at considerably less than the estimated cost. The Knowsley station cost £19,000; the Kirkby station will cost £500 less than that sum; and then there must be added to this £18,000, the cost of the pumping mains from Kirkby to Eccleston Hill and Brownedge reservoirs; £4,000, for parliamentary expenses; and £6,000, for compensation mains; as well as the charges imposed under the Act to satisfy the requirements of the Earls of Derby and Sefton. There are certain other works, included in the parliamentary estimate, which have not yet been carried out—principally the duplicate engines and house, which may not be required for many years, and will probably cost £20,000. From these figures, it will be seen that the Committee are a little less than £10,000 under the parliamentary estimate, apart altogether from the extra cost of providing compensation pipes and tanks.

WEYMOUTH GAS CONSUMERS' COMPANY.—In the report on the working of this Company in the six months ending June 30 last, which will be presented to the shareholders at their meeting next Thursday, the Directors state that notwithstanding the reduction in the price of gas which took effect from the 1st of January last, the consumption has remained almost stationary; the increase being very slight. The revenue from the sale of gas therefore shows a diminution as compared with the corresponding half of the previous year. The balance of profit on the revenue account is sufficient to pay the interest on the debenture bonds, and a dividend at the rate of 10 per cent. per annum on the ordinary "A" stock, and of 7 per cent. per annum on the ordinary shares; and at these rates (less income-tax) the Directors recommend the dividend for the half year to be declared.

THE PUBLIC LIGHTING OF UXBRIDGE.—In the JOURNAL last week reference was made to a discussion which took place at the meeting of the Uxbridge Local Board on the 31st ult., and to a suggestion made that a trial should be made with an oil-lamp. Complaints were made by several speakers of the inferiority of the lighting, but it was pointed out that this was a matter which it was quite within the power of the Board to alter, without resorting to oil. It would be well for the members to watch for a short time the progress of the Erith experiment, to which their attention was called before deciding on abandoning gas. In the meantime they may be reminded that the regulator burners in their public lamps only consume 3 cubic feet of gas per hour; and if, as was stated by one member, the Board do not wish to "go back to oil," the improvement in the street lighting might be easily effected by employing larger burners.

THE NORTHERN COAL TRADE.—There has lately been an improved demand for coal, and especially for gas coal. The shipments of coal from the Tyne Dock have been of late fully 12,000 tons weekly above those of last year, and the coals so sent out are chiefly gas coal, which is being very largely despatched to the Mediterranean ports. More gas coal is also being forwarded to London; but it will be a month before anything like heavy quantities are sent there. The local gas companies are now appreciably extending their requirements; and the Durham gas collieries are beginning to be well employed, though there are exceptions, and there is no pressure. Steam coals are rather quieter—about 7s. 6d. per ton being the price for best qualities; whilst the increased production of small coal has lowered its price to about 2s. 6d. to 3s., according to quality. The coke trade is fairly brisk; the quantities sent out being large. Gas coke still finds ready sale at the cement-works, and the price is firm, though the increased production must soon weaken it.

SUFFOCATION BY GAS.—Last Thursday, at the Sussex Arms, Sussex Street, Strand, Mr. Langham held an inquest upon the body of William Chaplin, aged 35, late of 16, Fort Road, Bermondsey, a gas-fitter, who was suffocated by gas on the previous Monday afternoon at Somerset House. The evidence of Joseph Heath, a bricklayer, was to the effect that he was assisting the deceased with some work in the basement of Somerset House. The deceased was engaged in taking off the cap of the gas-main, as they could not move the valve. Witness left him for ten minutes, and on his return found him lying helpless on the ground—to all appearance dead. The gas was escaping from the main, from which the deceased had removed the cap. Thomas Mann, foreman of works at Somerset House, stated that the deceased had been employed there about 2½ years, and on the day in question was instructed to examine the coals to see whether they were all in working order. The deceased ought to have turned off the gas in the street before examining the coals, and he went out to do so; but by some unaccountable reason he made a mistake, and turned off the wrong cock. Medical evidence was given which showed that the deceased's death was due to suffocation by gas; the jury returned a verdict of "Accidental death."

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

Though not exercising in the least degree a disturbing influence upon the working out of the gas-works transfer in Edinburgh and Leith, a question has arisen between the parties which they are unable to settle, and which Mr. Livesey, as sole Arbitrator, will be called upon to determine. The point is whether tools and implements which have been in use are to be paid for by the Commissioners, or whether they are included in the undertakings which they have taken over. As it was stated at the meeting of the Commissioners, it seemed to be a small matter—so small, in fact, as to be scarcely worth disputing over. Bailie Archibald's expression was that it referred to such articles as picks, shovels, barrows, &c. But the fight is not over such things as these. There are other and more valuable articles—such as meters—which have been in use, and have been returned to store; and if the Commissioners' reading of the Act of Parliament is right, then these, having been in "in use," must be held to be already the property of the Commissioners. Clause 20 of the Act says that the Commissioners are to pay, after valuation, for, among other things, "implements, meters, and pipes in store or in hand." It is a pity the expression was not made more explicit; but, as it is, Mr. Livesey will have no difficulty in determining, by precedent, how it should be read. Both Companies possess a valuable property in gas-stoves, many of them hired out, and others returned after hire. These will be lost to them if the reading of the Commissioners holds good.

At the meeting of the Aberdeen Town Council last Monday, the report of the Gas Committee stated that in the month of July there were three testings of the gas made by Dr. Matthew Hay; and these showed the quality to be 27·98, 28·75, and 29·12 candles respectively. Mr. Cook, a member of the Committee, in supporting the adoption of the report, said he thought these figures proved that Aberdeen was being provided with as good gas, and he thought better, than nine-tenths of the other towns were getting. He went on to point out that in their carbonizing process they were now getting about 100 cubic feet more per ton out of the coal than they did a year or two ago. Bailie Gordon remarked that the citizens never obtained better value for their money than at the present moment from the gas. The Committee's report was adopted. With reference to the agitation which has been going on outside in regard to the alleged increase of gas accounts, in the course of the proceedings Mr. Cook said he would not enter upon the consideration of Dr. Wallace's report [an abstract of which is given elsewhere to-day], although he said he was prepared to do so when the time came. The time, I consider, has come. If there is any foundation for the agitation, the Gas Committee have had sufficient opportunity to ascertain what it is; and their course should be to acknowledge that such was the case, and have it remedied. If, as I incline to think, there is not much foundation for the agitation, then the sooner it is checked the better, because its continuance is prejudicial to the confidence of the public in the gas supply. The Committee who are promoting the agitation are not slow to move. They have already objected to Dr. Wallace's report on the ground that the Doctor did not visit Aberdeen and investigate for himself, but was supplied by the Town Council with the information upon which he proceeded. As soon as the agitation arose, the Gas Committee were urged to face it, and show that its foundation was a very narrow one. The Committee have not, but the agitation Committee have themselves demonstrated this; because, after a public request that consumers who had been aggrieved by their gas accounts increasing in amount should send particulars to Mr. Adam Pratt, who may be called the leader of the agitation, Mr. Pratt has been able to furnish the Town Clerk with only 134 cases of alleged overcharge. There are more than 24,000 consumers' names in the books of the Gas Committee. In these circumstances, comment is needless. Mr. Pratt's latest move is an attempt to work up the public upon the fruitless question of the accuracy of gas-meters. In a letter to the local press, published yesterday, he states that, having had all his three meters tested, not one of them has been found to be correct. He does not state how much they are incorrect. Intelligent people will consequently estimate his communication at what it is worth, but ignorant people will probably not be able to read between the lines; and the agitation will thus go on.

At the meeting of the Alva Police Commission last Monday, the Gas Manager (Mr. Chalmers) reported that the new works were in a forward state, and that he anticipated they would be completed in another month. Satisfaction was expressed at this state of matters; and, on the suggestion of Mr. Chalmers, the Commissioners visited the gas-works on the following day and inspected them. The alterations, it is expected, will greatly facilitate the manufacture of gas, and reduce the cost of production.

In the death last week of Mr. Alexander Cruickshank, of Turfrie, the local Gas Company have lost a Manager who has shown much enterprise in the conduct of a small concern. When he was appointed to the post a number of years ago, he found the plant almost worthless and the revenue exceedingly small. He has succeeded in relaying nearly all the street mains; and in the course of his tenure of office he first doubled and then quadrupled the producing and storage power of the works. The Company's business thrives immensely under his management; and it now pays a respectable dividend—5 per cent., if I mistake not. Although carrying out all these improvements, it was noteworthy, and probably the reason of the prosperity of the Company, that they were so well financed that the price of gas was throughout kept at a moderate rate.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

At the last monthly meeting of the Kilsyth Police Commissioners, it was reported that the amount of gas passed through the station meter during the month of June was 175,000 cubic feet, as compared with 159,100 feet in the corresponding month of last year; so that there was an increase of about 16,000 feet. But from what cause the increase had arisen, none of the Commissioners were able to say. It was stated that the average amount of gas yielded per ton of coal was 9943 cubic feet, which was regarded by Mr. T. Wilson, Gas Engineer, of Coatbridge (who was present), as being exceedingly satisfactory. Mr. Frew spoke about the number of complaints regarding the gas; and Mr. Wilson, in reply, said that a great number of the complaints were due to faulty fittings and burners, and that in Coatbridge the burners were supplied free. The expense was not great; and the consumers obtained a better light. To do so in Kilsyth might cost the Commissioners from £3 to £4 per annum. The suggestion was talked over, and left with the Works Committee for consideration. From the contents of the annual balance-sheet which was submitted to the meeting, it was thought that the Commissioners would be warranted in taking 5d. per 1000 cubic feet off the price of the gas.

On Wednesday evening the annual report on the Kilmarnock gas undertaking was before the Town Council. Bailey Bain thought that it was a very satisfactory report, alike from the amount of progress shown and the reduction of 5d. per 1000 cubic feet in the price of the gas, which was double the quantity which had been anticipated by a number of the members. One gratifying feature in the report is the increased revenue

derived from the chemical works—a rise having taken place in the value of the residual products during the past year. The profit during the year was £3649. The report was adopted.

The ratepayers of the Dalmine division of the burgh of Clydebank are not altogether satisfied with the gas supplied to them in their ward, and with the price which they are charged for it. They lately appointed, at a public meeting, a Committee to inquire into the cheapest and best mode of lighting the streets during the coming winter. The Committee have since presented a very full report; and at the meeting where the report was received and considered, it was agreed that the Ward Committee should approach the Burgh Commissioners, and request them to open communication with the Glasgow Corporation Gas Trust; the Commissioners to lay the pipes, provided that the Gas Trust would supply gas at the same price as that at which it is supplied to the other wards of the burgh. In the event of this plan not being agreed to, a large and influential Committee was appointed to form a Company for the supply of oil gas to the ward—the electors considering this gas to be cheaper and better than that supplied by the Dalmine and Old Kilpatrick Gas Company. At the usual monthly meeting of the Commissioners, which was held on Thursday, it was reported by the Lighting Committee that they had received and considered the communication from the Dalmine ward, and that they had resolved that it was inopportune to make any approach to Glasgow for the present season, but to keep the matter in view for further action.

Every year, about this time, correspondence appears in the local newspapers regarding the lighting of the common stairs and closes in some of the suburban burghs. At present it is the southern burgh of Govanhill in which the grumbling is taking place in reference to the charge made upon the tenants for the gas consumed, as compared with that levied under similar circumstances on the stair tenants within the burgh of Glasgow. It is the practice in the suburban burghs to suspend the lighting for a portion of the year, and to charge the tenants at a higher rate for it than is charged for the city where the stair lighting is continued throughout the whole year. It is urged that this levying of a differential rate for stair lighting is continued with the view of helping to concuss the residents in the outside burghs into advocates of annexation to Glasgow.

At the last meeting of the Airdrie Town Council, it was suggested by Mr. Rankin that the street lamps of the burgh should be lighted continuously for the eight months (including moonlight nights), or lighting season, at the same rate as for six months' lighting, after deducting 60 days from the eight months for supposed moonlight nights, the total extra cost being only about £32 15s. If the Council would agree to that suggestion, he anticipated that the Gas Company would light the lamps at 9s. 4d. each, all the year round, in place of at 7s. for eight months—the total extra cost being the amount just mentioned. The Provost remarked that there was no doubt that they sorely needed light on some of the moonlight nights. The Council unanimously agreed to the suggestion; and it was remitted to the Fire and Lighting Committee to make the requisite arrangements with the Gas Company.

The ordinary shares of the Partick, Hillhead, and Maryhill Gas Company were quoted yesterday on the Glasgow Stock Exchange at 87s. 6d. per share, sellers; but buyers could not be induced to go beyond 82s. 6d. The preference shares were quoted by sellers at £6 10s.; and buyers were offering 5s. less per share.

At the recent ordinary meeting of the Helensburgh Police Commissioners, Mr. Whyte stated that the water-works extensions would be commenced at once; a contract having been settled with ex-Provost Murray of Maryhill, the amount of which was £3547. It was expected that the extensions would be finished early in the spring; and care would be taken that during the time that the operations were in progress, there would be an abundant supply of water always available.

During the past week the Glasgow pig iron warrant market has generally been quiet, but steady, with a moderate business doing from day to day. The fluctuations in price have ranged between 38s. 11d. paid on Tuesday and 39s. 5d. paid on Thursday; the closing price for Scotch iron yesterday being 39s. 4½d. cash buyers. There are now 87 blasting furnaces in actual operation, as compared with 84 at the same time last year.

Business continues steady in the local coal trade; but there is scarcely the same briskness in making sales as was shown two or three weeks ago. Shipments are fairly satisfactory at the Clyde and Ayrshire ports; and prices may still be said to rule firm. Main coal is quoted at 5s. 6d. to 5s. 7d. per ton f.o.b.

ABANDONMENT OF THE MANUFACTURE OF SULPHATE OF AMMONIA AT HEYWOOD.—At the meeting of the Heywood Town Council last Thursday, the Gas Committee recommended the acceptance of a tender for tar and ammoniacal liquor made at the gas-works during the ensuing year. It was stated that for the past year or two they had been converting the liquor into sulphate; but this year the Committee had decided to sell it, as they thought it would be more profitable to do so than to manufacture sulphate, particularly as the plant was not in very good order.

THE PUBLIC LIGHTING OF ACCRINGTON.—Mr. G. Hale, the Superintendent of the Lighting Department, has submitted to the Watch Committee of the Accrington Corporation a report as to the cost of lighting the street lamps during the winter months, without taking notice of the duration of moonlight. He estimates that if the lamps were lighted every night from the middle of August to the middle of May, the cost would be £1240—viz., gas, £965; and lighting and cleaning the lamps, £275. This is £319 more than the cost last year, when £690 was paid for gas, and £231 for cleaning, &c. As an alternative, he submitted a proposal for lighting the lamps night after night in the four months of November, December, January, and February, which will cost £202 more than was paid last year. The Committee decided to recommend the Council to light the lamps in the four winter months, irrespective of the various phases of the moon.

DORCHESTER GAS COMPANY, LIMITED.—In the report of the Directors of this Company to be submitted to the shareholders at their half-yearly meeting to-day, it is stated that the consumption of gas in the six months ending June 30 last showed a slight increase as compared with the corresponding period of last year. The consumption then was 12,144,800 cubic feet; and for the past half year it was 12,309,200—an increase of 164,700 cubic feet. The Directors consider that, as in the first six months of the year the consumption of gas, through the unpleasant weather and dullness of trade, was with most provincial companies less than in the similar period of the preceding year, even this small increase is satisfactory. The results of the past half-year's operations (with Mr. Frank Osmond at the head of the works) have been kept up to the usual standard; and there has been a further slight improvement in the prices of residual products. The profit is sufficient to pay the same dividend as in the previous half year—viz., 11 per cent (free of income-tax)—and carry over a small balance to the next account. The Directors therefore recommend the declaration of a dividend at this rate.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Aug. 11.

Sulphate of Ammonia.—While the tone of the market remains steady, the business is of a very limited compass; and the scarcity of foreign orders is very remarkable. When the shipments since July are taken into consideration, it seems to become self-evident that consumers abroad cannot be fully supplied; and the only conclusion to be drawn is that they methodically retard their orders, feeling either uncertain about their sales, in view of an unfavourable season, or preferring to take the orders for manures before buying the sulphate. Great uncertainty therefore prevails; and such a condition is not conducive to the favourable disposal of spot parcels, for which somewhat lower prices have consequently been accepted. It can only be repeated that the quantity offering is by no means large; but as long as it supplies the demand an improvement in prices is not within reach. The business this week at Hull has been principally at £11 10s.; but there are hardly buyers thereat to-day. At Liverpool and Leith £11 7s. 6d. is quoted.

LONDON, Aug. 11.

Tar Products.—This market is decidedly quiet; and buyers do not quite see their way to pay the advanced prices which are being quoted. Makers are somewhat indifferent, and do not press sales. The following prices may be taken as to-day's value: Tar, 17s. 6d. to 21s. per ton. Benzol, 90 per cent., 2s. 10d. per gallon; 50 per cent., 2s. 4½d. per gallon. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Creosote naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene 30 per cent., "A" quality, 1s. 5d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate is undoubtedly weaker, and sales have been made during the week marking a fall of nearly 10s. per ton—the current price being for sulphate of ammonia £11 5s. to £11 10s. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £28. Sal ammoniac, £30 per ton.

[From the Chemical Trade Journal, Aug. 11.]

Sulphate of Ammonia.—The sulphate of ammonia market is very dull; and prices are easier all round. Business has been done at Hull on Wednesday last at £11 10s.; and Leith and Liverpool may be stated at £11 8s. 9d. to £11 10s. Business at Leith continues brisk; over 460 tons having been shipped from this port during the week ending Aug. 4, the major portion of which has been forwarded to Hamburg. Beekton price is now £11 12s. 6d., though £11 13s. 9d. is reported to be asked for London outside makes.

Tar Products.—All tar products remain *in statu quo*; at least in so far as prices are concerned. If there is any tendency to change in any way, it is towards weakness in several articles. Benzoles keep up their value; and to-day's price may be taken as 2s. 4d. to 2s. 10d., though it is possible that large orders may be treated more leniently by sellers, especially for forward business, where all is mystery. Benzol, keeping up so well, has made it good for the gas industry. Wigan tar has just been let for 26s. 6d. at the gas-works; so it is pleasant to find somebody thinking that the old horse is not played out yet. Crude carbolic, following in the wake of crystal carbolic, is decidedly weaker; and 3s. 4d. for crude is not now a tempting price for buyers. Pitch stands much the same as in our previous reports but there has been a fair business doing lately.

THE PRICE OF GAS AT RAMSBOTTOM.—At the last meeting of the Ramsbottom Local Board, Mr. Whitaker, in accordance with notice, drew attention to the price now charged for gas by the Ramsbottom Gas Company. He said he did not wish to press the Company too hard, but thought they might sell gas at the same rate as other companies in the neighbourhood. The Bury Corporation were at present supplying some portions of Ramsbottom with gas at 2s. 11d. per 1000 cubic feet, and in the same district the Ramsbottom Company were charging 3s. 11d. In answer to a question by a member, the Clerk said the only power the Board had was to buy the gas undertaking. Eventually a Committee was appointed to interview the Directors of the Company at their next meeting.

FATAL ACCIDENT AT THE LEICESTER GAS-WORKS.—A workman named Wale, 21 years of age, met with a shocking death at the Leicester Gas-Works, on Thursday, the 2nd inst. He had been in the employ of the Gas Department as a labourer since last September, and on the day in question was engaged in painting the ironwork of the liquor tank. Several other men, who were working near, heard a splash, and on turning round found that Wale had disappeared. A ladder was immediately procured, and the discovery was made that he had fallen through the manhole into the tank, which is 12 or 14 feet deep, and contained about 8 feet of tar and ammoniacal liquor. Within a minute or two of the accident assistance was rendered, and an attempt was made to save the unfortunate fellow; but before the body could be recovered death had taken place. At the inquest held on the following day, it was suggested that Wale endeavoured to cover up the manhole unassisted. This was the work of two men; and the regulations prohibited anyone attempting to do it alone. Deceased was a good and steady workman. The jury returned a verdict of "Accidental death;" the Manager of the works (Mr. A. Colson, Assoc. M. Inst. C.E.) stating that he had already taken precautions which would prevent the recurrence of such an accident.

NEW WATER-WORKS AT THORNTON.—New water-works constructed by the Thornton Local Board were opened last Wednesday by the Chairman of the Board—Mr. D. Craven. Hitherto the supply of water to the village has been obtained entirely from the Bradford Corporation and from private wells. In the year 1866 sanction was obtained by the Board to a loan of £5000 for the construction of a storage reservoir, into which the Corporation have run the water for the supply of the village; and since then there has been little modification of the system until the present time. Thornton, however, stands at a very high level, and during the drought of last year the failure of the Corporation adequately to supply the village was so marked that the desirability of constructing works for the supply of the Local Board district solely was mooted. The notion appears to have been favourably received; and Mr. J. Craven, M.P., gave substantial encouragement to the proposal by making a gift to the Board of between three and four acres of ground on the high land known as Hill Top, in Thornton. The plot contains a quarry, into which the water from a large number of springs finds its way; and the Board have sunk a shaft at the bottom of the quarry and erected a pumping-engine for raising water from it. The works are therefore of a very modest character; but the supply to be obtained by their means promises to be both copious and of good quality. The opening ceremony consisted in starting the pumping-engine, which was done by Mr. Craven, in the presence of several members of the Local Board and some visitors. After the ceremony, the company dined together in celebration of the event.

THE LARGEST GAS EXHAUSTERS IN THE WORLD.—Messrs. R. and J. Dempster, of Newton Heath, Manchester, have in hand an order for three exhausters, each capable of passing a million cubic feet of gas per hour.

THE DISPOSAL OF GAS PROFITS AT WORKINGTON.—At the meeting of the Workington Local Board last Tuesday, the Chairman (Mr. G. J. Smith) moved that the price of gas be reduced from 2s. 11d. to 2s. 6d. per 1000 cubic feet. He said he thought it would still further develop and increase the sale of gas if this reduction were adopted. Mr. Towers seconded the motion. Mr. Iredale moved, as an amendment, that an annual sum of £600 be paid from the gas-works profits to the credit of No. 1 district of the town, to partially meet the heavy expenditure of this district in redeeming the old debt existing at the time of the Provisional Order of 1878. He thought this was only fair to the district; and if the price of gas was reduced to 2s. 6d. there would not be sufficient profit left for this purpose. The amendment was carried.

THE PUBLIC LIGHTING OF YORK TOWN.—A further step was taken last week by the Lighting Inspectors of York Town in the direction of lighting the public lamps with oil (see *ante*, p. 251). At the meeting of the Inspectors last Wednesday, they had received tenders from Messrs. Defries, and also from the Stringfellow Patent Company, of Birmingham; and it was decided to make further trial with the Company's lantern, with a view to its adoption. The patentee's offer was to convert the old lantern heads (square ones), and to find oil, and keep clean, light, and extinguish the lamps for the first year, at £2 per lamp; second and third years, £1 5s. per lamp. With respect to the round-headed lamps, he offered to put on a new lamp head, similar to one produced, at an additional charge of 3s. 4d. per year. If the Board decided to keep the lamps at the end of three years, they were to pay a royalty of 5s. per lamp in one lump sum for the use of the patent.

BURY ST. EDMUNDS GAS COMPANY.—On Friday, the 3rd inst., the 78th half-yearly meeting of the Bury St. Edmunds Gas Company was held at the gas-works—Mr. W. Salmon presiding. The report of the Directors was read; and the recommendation that a dividend for the past half year, free from income-tax, of 12s. per £10 share on the 1849 capital, 9s. 6d. per share on the 1859 capital, and 9s. per share on the 1879 capital, be paid, was adopted. The half-yearly statement of accounts to June 30 showed a balance of £2577 brought forward, and £2392 carried forward after appropriating £1620 to the payment of dividends. The principal receipts were: For gas and meters, £5998; coke, £882; ammoniacal liquor, £235; tar, £123; interest on reserve fund, £91. The principal expenses were: Coals and freight, £1477; wages and salaries, £928; rates and taxes, £790; repairs, £113. The report was adopted.

BARNET DISTRICT GAS AND WATER COMPANY.—In the report of the Directors of this Company, which will be presented at the half-yearly general meeting of shareholders next Thursday, dividends at the rates of 7 per cent. per annum on the "A" and "C" stocks, 6 per cent. per annum on the "B" stock, and £4 18s. per cent. per annum on the "D" (water) capital are recommended. The business of the Company continues to increase. The price of gas to private consumers has been reduced 3d. per 1000 cubic feet (from 4s. 6d. to 4s. 3d.) as from Lady-day last, and the price of gas, supplied on the average meter system, for the public lighting has been brought down to 4s. per 1000 cubic feet. With regard to the water portion of the undertaking, it is stated that the sinking of the new well, the erection of the engine-house, and the placing of the pumps in position are still in progress. In accordance with an agreement with the Barnet Rural Sanitary Authority, mains have been laid for the supply of water to the village of South Mimms. Reference is made to the accession of Mr. James Galsheir, F.R.S., to the chair, *vice* Mr. J. F. Bontems, whose recent removal by death, under painful circumstances, is referred to elsewhere. Accompanying the report are the accounts, prepared by the Secretary and Accountant (Mr. Alfred Lass, F.C.A.), and certified by the Auditors (Messrs. F. Lennard and A. G. Hounsham).

THE PUBLIC LIGHTING BY OIL AT ERITH.—At the meeting of the Erith Local Board last Wednesday, the subject of the public lighting of the district by oil, an account of which was given by Mr. R. P. Keys, in his letter which appeared in the last issue of the JOURNAL, was considered, on the presentation of a report by the Lighting Committee. The Committee (consisting of the entire Board) met on the 27th ult., when Mr. Defries, one of the contractors for the oil lighting, was present. Although the night was a very boisterous one, the Committee made a thorough inspection of the district, and took notes of the details and work requiring the attention of the contractors; Mr. Defries promising to do all he could to make the lighting perfect in every particular as speedily as possible. The Committee expressed satisfaction with the oil-lights, where they had been properly turned up; though, through inexperience on the part of the lamp-lighters, this was not done in many cases—a great deal more strength, care, and skill being needed as compared with the lighting of gas-lamps. The Committee suggested that the Board should fix the 15th inst. as the date on which they would require the contractors to have all the lamps burning according to the terms of the contract; the Committee to again inspect the district, and invite Mr. Defries to be present. This was agreed to. [It should be pointed out that in Mr. Keys's letter, above alluded to, the hour at which he arrived at Erith on the evening of the 28th ult. was given as six, instead of eight.—Ed. J. G. L.]

EAST WORCESTERSHIRE WATER WORKS COMPANY.—The eighteenth meeting of the shareholders of this Company was held on Thursday at the offices, Waterloo Street, Birmingham—Lord Windsor presiding. The report stated that during the six months ending in June last, 150 additional services had been laid on, which brought the total up to 16,022. The Directors wished to impress upon the shareholders the necessity of doing something to convert the Company from a non-paying concern to one paying a dividend. All the capital was paid up; and, in consequence, the shares were at a discount, because they had no money to carry out the work which was called for. There was £800 standing to the credit of revenue account, which was more than equal to a dividend of 1½ per cent. on the whole capital. In order to enable the Directors to carry out the extensions, they proposed to issue one new share for every five of the original issue, and only call up £5 on each share. This would help them to carry out the work desired, and to pay a dividend, and would enable them to save £120 they now had to pay as interest. The Chairman, in moving the adoption of the report, said that he wished to draw the attention of the shareholders to the important proposal which had been made in the report. It was hardly necessary for him to remind the shareholders of the present condition of the Company. It was a very serious one, and more capital was wanted. Several applications for extensions had been received, and were engaging the attention of the Directors; and it was desirable to comply with these applications. Distinct advantages would be derived by all from the adoption of the proposals made. The dividend at first would be small; but the signs were encouraging, and they might proceed. He trusted the proposals would be heartily accepted. Mr. C. P. Noel seconded the motion, and endorsed the remarks of the Chairman. Dr. Gibbs Blake supported the motion, which, after a few questions had been asked, was adopted unanimously.

THE DISPOSAL OF METROPOLITAN SEWAGE.—At the meeting of the Metropolitan Board of Works last Friday, the Works Committee reported that they had had before them a suggestion by Sir Henry Roscoe, that an exhaustive examination—chemical, physical, and microscopical—should forthwith be made of the condition of the foreshores of the Thames from Barking down the river to the mouth, including the whole of the estuary. He considers it to be of great importance, in view of the proposal to carry the sludge out to sea, and of questions which may arise thereon, to be in possession of scientific data of an accurate character as to the condition of the foreshores at the present time. Sir Henry suggests that Sir Joseph Bazalgette should be instructed to send an assistant to examine and report from an engineering point of view, whilst the Board's Chemist (Mr. W. J. Dibdin, F.I.C., F.C.S.), and his assistant, together with Sir H. Roscoe's assistant, who he states has had experience in such work, should be called upon to make the chemical inquiry. Sir Henry, for his part, will undertake to superintend the whole work, to draw up instructions as to the details of work to be done, and to report to the Board on its completion. This was agreed to.

CROYDON CORPORATION WATER SUPPLY.—At the meeting of the Croydon Council on Tuesday last week, Mr. Morland, in moving the adoption of the Water Committee's report, took the opportunity of referring to the cost of the new water-works, the inauguration of which by the Archbishop of Canterbury was noticed in the JOURNAL last week. He said that, as the Council were aware, certain difficulties arose in connection with the sinking of the well, which caused an expenditure above the estimate of £6400. The original estimate for the whole work was £46,000; and if they added to this the further expense of £6400, they arrived at £52,400 as the estimated expenditure on the whole work. He expected the actual expenditure would be about £52,000, which was exceeding near the estimate. He should also observe that a great deal of additional work had been done, which was not reckoned for in the original estimate. The engine-house had been made nearly twice the size originally intended, in order that, whenever they required another engine (as they were pretty sure to do in a few years time), one could be put in the present house without incurring more outlay for building. They had also expended a large additional amount on new mains. The Council desired the extension of the mains in Norwood, with the view of supplying water there for sanitary purposes; and the mains from the reservoir had been made much larger than at first estimated for. They had, in fact, in this respect done half as much more work than was originally expected; but the cost had not been proportionately more—the price of iron having been so low that they were able to do more work for the money than at first anticipated.

† Next dividend will be at this rate.

SOUTH STAFFORDSHIRE WATER-WORKS COMPANY.—The following is the report of the Directors, to be submitted to the proprietors at the meeting to be held at Birmingham, on the 23rd inst.:—"The number of houses laid on during the half year ended June 30, 1888, was 1500; making the total supplied 65,641. The gross amount of water-rates for the half year was £33,973 10s. 9d., as against £32,707 2s. 2d. in the corresponding period of the previous year. After providing for interest on debenture stock and preference stock, the amount remaining for division (including £2299 7s. 6d., the balance brought from last half year) is £13,130 11s. 3d.; and your Directors recommend the declaration of a dividend for the half year on the ordinary stock at the rate of 5 per cent. per annum, less income-tax. The amount required for the dividend being £12,433 14s., there will remain £696 17s. 3d. to the credit of next half year. The Directors regret that the Bill in Parliament, promoted under the authority of the meeting of proprietors held on the 16th of February last, was defeated in the House of Commons, although it had been previously passed, after a lengthened inquiry, by the House of Lords.

POLLUTION OF A BROOK WITH GAS-WORKS REFUSE.—At the Bromsgrove Petty Sessions last Tuesday, before Messrs. Smallwood and White, the Bromsgrove Gas Company were summoned for allowing, on the 29th of May last, liquid matter to flow into the Spadesbourne Brook, a tributary of the Severn, in such quantities as to kill fish. Mr. F. Holyoake appeared for the Severn Conservators; and Mr. J. R. Horton defended. Alfred Lacy, a stoker in the employ of the Company, was called as a witness against his employers; but his evidence went to show that no liquid ran from the Company's works into the stream, nor was it possible for anything to pollute it. There was but one drain connected with the brook; and this received only exhaust steam and the water which the men had used for washing themselves. All other refuse entered the main drainage. Sergeant Emms, who had examined the gas-works in company with Sergeant Cooper, gave a very different version of the state of affairs, and alleged that Lacy had told him the Manager (Mr. Wheeler) had recently given instructions that the refuse from a certain pipe should be caught in buckets. Two witnesses deposed to seeing boys taking dead fish from the brook. Most of them were small; but one weighed about 1½ lbs. Cooper, the water bailiff, having given evidence, Mr. Horton addressed the Bench for the defence, contending that nothing of an offensive character went down the drain which ran into the brook. The residual tar was a valuable product; and it was not likely the Company would waste it. Some of it was used for heating the retorts. The Manager and another witness gave evidence to show the impossibility of polluting the stream as alleged; and it was stated by two men that they had seen boys getting dead fish from the brook 200 yards from the Company's works. The landlord of a neighbouring public-house testified to a pail of tar being overturned in his yard on the 19th of May, and to the contents being swept into the brook. The Bench nevertheless fined the Company £1, and £2 7s. 6d. costs.

THE LIGHTING OF THE TEES BY GAS.—At a meeting of the Tees Conservancy Board last Wednesday, the Secretary (Mr. Amos) read a communication he had received from the Trinity House to the effect that a Committee of the Elder Brethren had visited the Tees, and did not see any objection to the adoption of Pintsch's system of lighting by compressed gas for any station on the river at which it might appear to the Conservancy Board to be desirable. They suggested, however, that in the adoption of gas-buoys it was essential that a spare buoy should always be available in case of accident. A resolution was submitted, authorizing the Committee to carry out the lighting scheme so far as it had been approved by the Board; and this was agreed to.

THE SOWERBY BRIDGE LOCAL BOARD AND MESSRS. WHITWORTH AND CO.—The difference which the Local Board of the Sowerby Bridge district have had with Messrs. Whitworth and Co., Limited, from whom they recently bought the gas-works situated at Luddenden Foot, is in a fair way of settlement. It will be remembered that Messrs. Whitworth claimed to be supplied with gas at the same price as was being charged in Sowerby Bridge itself; and, failing this, they threatened to resume the manufacture of gas for their own works and tenants. At the last meeting of the Gas Committee, however, a letter was received from the firm, offering to pay 3s. per 1000 cubic feet for gas supplied to them; and the Committee resolved—"That the offer be accepted—viz., 3s. per 1000 cubic feet net, from the March quarter, so long as the gas remains at the present price, and that the price up to that time be 3s. 9d. per 1000 feet, less the usual discount." The resolution was confirmed by the Board at their last meeting.

TRURO WATER COMPANY.—At the half-yearly meeting of the Truro Water Company held last Wednesday, under the presidency of Mr. A. C. Williams, the Chairman congratulated the shareholders on the gradual improvement in the position of the Company. On revenue account the balance had risen from £321 to £334; and there had been an increase in water-rents from £447 to £470. On the profit and loss account he was glad to say there was a great improvement. The balance against them last half-year was £133, which had been cleared off altogether, and there was now a credit balance of £310. It was the first time they had "turned the corner;" and it represented on a capital of £16,000 about 2 per cent. profit on the half year. They might congratulate themselves on this. It was a day they should remember; and he hoped it was an earnest of what would be done in the future. The Directors had gone into the matter of providing additional storage at the reservoir and works. They had had two schemes before them of making reservoirs to store a two months' supply, supposing the rivers ran dry. The cost of one scheme would be about £1200, and of the other about £1500, exclusive of the land. At present they had not come to any definite conclusion on the matter. There was an ample supply now; but the time would come when they would have to make some such outlay. The Directors' report was adopted.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,

ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS &c., &c.

Catalogues and Testimonials on application at the above address.

OXIDE OF IRON.
THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 850,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 161 to 163, Palmerston Buildings, Old Broad Street, London, E.C.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, 158, Palmerston Buildings, Old Broad Street, London, E.C.

CANNEL COAL, &c.
JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 50, St. Andrew Square, EDINBURGH, } SCOTLAND.
No. 54, BERNARD STREET, LEITH,

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE AND CO. 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56, MILLBANK STREET, LONDON, S.W.

[Telegraphic Address: "PRECISION LONDON,"]
Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gasholders and Meters, Registering and other Gauges, &c., &c.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.
JOHN NICHOLSON & SONS, Chemical

Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour.

Highest References and all particulars supplied on application.

ACETATE OF LEAD BOOKS.
TEST Papers and Solutions for Gas-

Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham.
Analysis of Coal, Oxide, and all Gas Materials.

GAS-WORKS of any magnitude leased, at premiums ranging from 5 to 10 per cent. according to the size of the Works. Gas-Works erected or re-modelled upon the most modern principles.

Address GEORGE WELLER, Gas Engineer, St. Ives CORNWALL.

CROWTHER BROTHERS solicit a trial of their **IMPROVED SYSTEM OF RETORT FETTING**. Can guarantee them to heat well, and the bottom Retorts to Carbonize as much Coal as those at the top. Constructed to burn Tar or Coke. Can be altered in a few minutes.

For particulars, write to 384, Mile End Road, London, E.

"EXCELSIOR" TAR-BURNER.

TAR worth 30s. per ton for Burning. Come and see and believe, or send for Burners complete, with Instructive and Descriptive Pamphlet, 16s. 6d.

Estimates given for Fixing and Starting, and satisfactory working guaranteed on application to THOS. BURTONSHAW, Gas-Works, CHIPPING NORTON.

A CIVIL Engineer, Assoc. M. Inst. C.E.,

with over Twenty years' experience in Water Supply, in all its branches—including Shaft Sinking and Boring—desires an Engagement. Highest testimonials and references.

Address S., 199, GOLDHAWK ROAD, W.

A YOUNG Man (aged 22), the Son of a Gas Manager, will be glad to meet with an appointment as **CLERK, COLLECTOR, or MANAGER** for Gas-Works at home or abroad.

Good references; and security given. Address No. 1617, care of Mr. King, ff, Bolt Court, FLEET STREET, E.C.

SITUATION wanted, as **Manager of**

Small Gas-Works. Well up in Carbonizing, Fitting, Meters, &c. Security if required. Address A. B., 7, Durden Street, LIVERPOOL.

WANTED, a Situation as Gas-Fitter,

Meter Taker and Repairer, or Working Foreman. Ten years' good testimonials. Address M. R., care of Mr. Metcalfe, 3, Park Court, Park Lane, LEEDS.

WANTED, a Situation as Working

MANAGER in Small Works. Thoroughly understands the Carbonizing Department, Reading Indices of Meters, Fixing Meters, Stoves, &c., Laying Mains and Services, and all Repairs attached to Gas Plant, age 39, married, abstainer.

Address No. 1630, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

WANTED, a Man to Manage a Private

Gas-Works, for large mansion near Sevenoaks. Apply, first by letter, to SMOODE AND CO., Gas Engineers, 48, Osnaburgh Street, LONDON, N.W.

WANTED, Second-hand Tar-Tank, in

good condition, about 12 feet long, 6 feet wide, and 6 feet deep. Apply to Gas-Works, Rugeley, STAFFS.

WANTED, a Working Stoker for a small

Country Gas-works in the Midland district, within 48 miles of London. Must be a good Carbonizer. Satisfactory testimonials as to competency and steadiness required. Wages 24s. per week, with house, coal, and gas free.

Address, stating age, to G. C., Post Office, Luton, BEDS.

ASSISTANT Secretary required in an

Australian Colony. Must be experienced in similar employment in large Gas Companies in Great Britain, a thorough Accountant, skilful, and of good business tact, not over 35 years of age, and prepared to supply satisfactory proof of competence and reliability. Salary, subject to above qualifications, £500. All communications will be considered confidential; and those which contain a sufficient answer to this and the former advertisement will be forwarded, for further consideration, per mail of the 24th inst.

Address No. 1628, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

FOR SALE—A good Second-hand Gas-

HOLDER, 30 feet diameter by 12 feet deep: Five Columns, Trellis Girders, and Counterbalance Weights, in perfect condition. Also small CAST-IRON TANK and GAS HOLDER, 20 feet diameter by 12 feet deep. Apply to WILKIE AND CO., Gas Engineering Works, Commercial Road, EXETER.

FOR SALE—Two Purifiers 6 ft. by 4 ft.;

three Tiers of Sieves, with 4-inch Valves, Connections, and Lifting Gear. Situate at Thame Gas-Works. Also some 4-inch DIP and ARCH PIPES. Apply to Mr. COOPER, Gas-Works, Banbury, OXON.

FOR SALE, Four Purifiers 12 feet square

by 4 ft. 6 in. deep, with twelve 14-inch Valves Connections and Lifting Gear complete. Can be seen at work at the Stourbridge Gas-Works. Also a double-action PUMP EXHAUSTER, for 10,000 feet per hour; made by Hanna, Donald, and Wilson. Apply to W. NORTH, Gas-Works, STOURBRIDGE.

TO TAR AND ROSIN DISTILLERS.

FOR SALE—Two Wrought-Iron Tar STILLERS, 1800 and 1600 gallons; three Cast-Iron ROSIN STILLERS, with Covers and Condensers complete, and all in good condition; also several Wrought-Iron OIL TANKS, from 800 to 7000 gallons. Must be immediately sold and cleared for alterations of Premises. No dealers.

Apply to F. MORRIS, Tar and Rosin Distiller, Plough Bridge, Rotherhithe, LONDON.

OFFERS invited for "Journal of Gas Lighting," 1854 to 1897 inclusive, bound. Gas Institute Transactions, 1882 to 1887 inclusive. Report of British Association of Gas Managers, 1881; and Reports of Gas Engineers and Managers' Associations, 1884 to 1887 inclusive. Also Vol. I. of "King's Treatise." Apply at the Gas-Works, DUDLEY.

NEW ROMNEY GASLIGHT AND COKE COMPANY, LIMITED.

ISSUE OF 400 SHARES OF £5 EACH.

APPLICATIONS are invited for the remainder of above SHARES. Allotment in order of application.

WM. ALLEN, Secretary.

New Romney, Kent.

THE Truro Gas Company invite Offers for purchase of about 40 tons of SPENT OXIDE. Sample sent free on application to the Manager.

CORPORATION OF SOUTHPORT.

THE Gas Committee are prepared to receive TENDERS for all the WROUGHT and CAST IRONWORK required for a Retort-Bench containing 48 through Retorts.

Specification and plans may be seen on application to the Engineer, Mr. John Booth, or copies of the same will be supplied at a charge of half-a-guinea per set.

Tenders, endorsed "Retort-Fittings," to be in the hands of the undersigned not later than Monday, the 3rd of September next.

J. H. ELLIS, Town Clerk.

Town Hall, Southport, Aug. 4, 1888.

SOEWERY BRIDGE LOCAL BOARD OF HEALTH.

(GAS DEPARTMENT.)

THE Gas Committee of the Sowerby Bridge Local Board of Health invite TENDERS for the purchase of the surplus TAR which may be produced at their Gas-Works, at Sowerby Bridge and Luddenden Foot, during One or Two years, from the 1st of September, 1888.

Tenders to be sent in not later than Tuesday, Aug. 21, 1888.

Specifications and forms of tender can be obtained by applying to the Manager, at the Gas-Works.

The Gas Committee do not bind themselves to accept the highest or any tender.

JOHN MARSLAND, Engineer and Manager. Gas-Works, Sowerby Bridge, Aug. 2, 1888.

HEREFORD CORPORATION.

(GAS-WORKS DEPARTMENT.)

TO TAR DISTILLERS AND OTHERS.

THE Gas Committee are prepared to receive TENDERS for the surplus TAR produced at their Gas-Works for a term of One, Two, or Three years, from the 1st of January, 1889.

Particulars and form of tender can be had on application to the undersigned.

Sealed tenders, addressed to the Chairman of the Gas Committee, Mansion House, Hereford, and endorsed "Tender for Tar," must be sent in not later than the 1st of September, 1888.

The Committee do not bind themselves to accept the highest or any tender.

By order,

WILLIAM PARLEY, Gas Engineer and Manager. Gas-Works, Hereford, Aug. 9, 1888.

WALLASEY GAS-WORKS.

TO TAR DISTILLERS AND OTHERS.

THE Wallasey Local Board are prepared

to receive TENDERS for the purchase of AMMONIACAL LIQUOR (about 2200 tons per annum), and also of the surplus GAS TAR (about 1000 tons per annum), produced from time to time at their Gas-Works, Great Float, near Birkenhead, during a period of One, Two, or Three years from the 30th of September next.

Any further information may be obtained on application to Mr. H. Ashton Hill, Gas and Water Manager to the Board.

Sealed tenders, endorsed "Tar, &c." and addressed to The Chairman of the Gas and Water Committee, to be left at my Office as below, not later than Five o'clock in the afternoon of Monday, the 27th inst.

The Board do not bind themselves to accept the highest or any tender.

By order,

WM. VICKERS, Clerk to the Board. Public Offices, Egremont, Cheshire, Aug. 9, 1888.

TENDERS FOR GAS COAL.

THE Gas Committee of the Stockton Corporation invite TENDERS for the supply, in whole or in part, of 23,000 tons of clean, well-screened, or TREBLE NUT GAS COAL, similar in quality to sample wagon, to be supplied to the Gas Committee if so requested.

The Coal to be delivered free from all dues in the Gas-Works Siding, in a dry state, free from dirt, shale, or other impurities, and in such daily quantities as may from time to time be directed by the Gas Manager.

Payments will be made monthly after each Council meeting. The Gas Committee do not bind themselves to accept the lowest or any tender.

Tenders, specifying the quantity and description of Coal offered, to be sealed and endorsed "Tender for Gas Coal," to be lodged with me on or before the 22nd of August, 1888.

WM. FORK, Manager.

Corporation Gas-Works, Stockton-on-Tees, Aug. 1, 1888.

BROMLEY GAS CONSUMERS' COMPANY.

NOTICE is hereby given that the ORDINARY HALF-YEARLY GENERAL MEETING of this Company will be held at the Bell Hotel, Bromley, Kent, on Thursday, the 30th day of August inst., at Six o'clock precisely, to receive the Report of the Directors, the Balance-Sheet confirmed by the Auditors, to declare a Dividend, and for General Business.

The Transfer Books will be closed on the 16th day of August until after the Meeting.

By order of the Board,

GEORGE H. OSBORN,

Secretary and Manager.

Offices at the Works, Bromley, Kent, Aug. 14, 1888.

TOTTENHAM AND EDMONTON GASLIGHT AND COKE COMPANY.

NOTICE is hereby given that the Annual

ORDINARY GENERAL MEETING of the Shareholders in this Company, will be held at the Company's Offices, Willoughby Lane, Tottenham, on Saturday, the 25th day of August inst., at Three o'clock in the afternoon precisely, to receive the report of the Directors, the Statement of Accounts for the Half Year ended the 30th of June, 1888, to declare Dividends for the same period, and for the Election of Two Directors and an Auditor for the ensuing year, and for transacting such other business as the Act of Parliament directs.

The Transfer Books will be closed from the 11th to the 27th day of August, both days inclusive.

By order of the Board,

JAMES RANDALL, Secretary.

Offices of the Company, Willoughby Lane, Tottenham, Aug. 10, 1888.

MITCHAM AND WIMBLEDON DISTRICT GAS LIGHT COMPANY.

(INCORPORATED BY ACT OF PARLIAMENT, 1867.)

NOTICE is hereby given that the FORTY-THIRD ORDINARY HALF-YEARLY GENERAL MEETING of the Proprietors of this Company will be held in the Board-Room at the Works, Mitcham, in the County of Surrey, on Tuesday, the 28th day of August inst., at Three o'clock in the afternoon precisely, to receive the Report of the Directors, and a Statement of the Accounts for the Half Year ended the 30th day of June last, to declare a Dividend, and for General Business.

The Transfer Books will be closed from the 13th inst. until after the meeting.

By order,

BENJAMIN GREEN,

Secretary and Manager

Board-Room, Mitcham, Surrey, Aug. 7, 1888.

TO INVENTORS AND PATENTEES.

MR. W. H. BENNETT having had considerable experience in matters connected with Gas, Water, and Sanitary Improvement, begs to say that he continues to assist Inventors in the perfection of their designs, and to obtain for them PROVISIONAL PROTECTION, whereby their Invention may be secured for Twelve months; or LETTERS PATENT, which are granted for Fourteen Years.

Patents completed, or proceeded with at any stage, thereby rendering it unnecessary for persons resident in the country to visit London.

Patents procured for Foreign Countries. Information as to cost, &c., supplied gratuitously upon application to the Advertiser, 22, Great George Street, WESTMINSTER.

FIDELITY GUARANTEE.

OCEAN & GENERAL GUARANTEE COMPANY, LIMITED.

Instituted to provide Security on the fidelity of persons holding positions of Trust.

BONDS granted on behalf of Secretaries,

Clerks, and Collectors to Gas and Water Companies at lowest rates of Premium. Large Reductions made when several Officials in one Company are Guaranteed.

The Bonds of the Company are accepted by the Lords Commissioners of H. M. Treasury, Local Government and Inland Revenue Boards, Board of Trade, &c., &c. Quotations invited.

Apply to RICHARD J. PAULL, Secretary.

Head Office: Mansion House Buildings, London, E.C.

JAMES OAKES & CO.,

ALFRETON IRON-WORKS DERBYSHIRE,

AND

WENLOCK IRON WHARF, 21 & 22, WHARF ROAD, CITY ROAD, LONDON, N.,

Manufacture and keep in Stock at their Works (also large stock in London)

PIPES and CONNECTIONS, 1½ to 48 inches in diameter; and make and erect to order RETORTS, PURIFIERS, and TANKS, with or without planed joints, COLUMNS, GIRDERS, SPECIAL CASTINGS, &c., required by Gas, Water, Railway, Telegraph, Chemical, Colliery, and other Companies.

NOTE.—Makers of HORSLEY'S PATENT SYPHONS. These are cast in one piece, without Chaplets; doing away with bolts, nuts, and covers, and rendering leakage impossible.

TUESDAY, AUGUST 21, 1888.

A DISCUSSION ON GAS-BURNERS.

THERE was an interesting discussion (given elsewhere), at the North British Gas Managers' meeting, upon Mr. Geo. R. Hislop's paper on gas-burners, already published, in the course of which one or two observations were made that suggest a few words of comment. Mr. A. Macpherson, of Kirkcaldy, displayed righteous indignation against the itinerant sellers of gas-burners, who victimize ignorant gas consumers by selling to them, at 4d. or 6d. each, common articles of this description worth only 4s. 6d. a gross. The mischief done by these men is doubtless still considerable; but there is reason to believe that the modern practice of hiring out gas-stoves, &c., by Gas Companies has had a marked influence upon the trade of the gas-burner pedlars. We are assured that these gentry are not by any means so troublesome as they used to be, when consumers thought that the Gas Companies, who left their

internal fittings "severely alone," were their natural enemies. Time was—and not so very long ago—when a peripatetic vendor of gas-burners was sure of a sale for any rubbish that he chose to describe to his victims as disliked by the Gas Company. It was almost universally believed that the vendors of gas were pleased to see their product wasted, so long as it had passed through the consumer's meter. We do not say that this idea is extinct in all places, for there is nothing so long-lived as ancient error; but the most pessimistic student of humanity in these little manifestations must admit that there is a general improvement. Of course, it may not be all traceable to the cause we have named; but it would not be right to restrict this influence to its immediate effect, and there is reason to believe that the view we have stated is amply justified. Hawking gas-burners is not so popular a resource of the lazy or "out-of-work" mechanic as it was; and those who still take it up are compelled to deal in a better article. The so-called "duplex," or double-jet batwing burner, is still the main stock-in-trade of these itinerant vendors; but while these appliances find a place in respectable exhibitions it would be unfair to blame the pedlars too severely for trafficking in them. Self-lighting burners, generally well made, and good enough of their kind, are also hawked extensively; although how the vendors manage to persuade their patrons of their superior economy is a mystery. Economy is the great pretension under cover of which this trade is prosecuted. The burner only costs a few pence, or a shilling at the outside; and it is warranted to save so many shillings, or even pounds, in the course of a year! Another thing worthy of remark is that as the hawkers have become fewer, so there is less variety in their wares. The day of *bizarre* forms in gas-burners is past, never to return. The high-class Argands and regenerative gas-lamps shown in public offices, banks, and the better class of shops, have had their effect in educating the public mind in the principles which they exemplify. The utmost the wandering pedlar can do is to lay claim to a modicum of their excellences for his humble wares; and therefore, relic of a superstitious age as he is, he cannot do as much injury as lay in his power when there was little or nothing outside the gas-works to counteract him.

While referring to the discussion upon Mr. Hislop's paper, it may perhaps be worth while to draw attention to a term used by Mr. Macpherson with regard to some remarks made by Mr. W. Key upon the influence of the size of the internal bore of a burner on the illuminating power of the gas-flame. The point was well brought out by Mr. Key; and Mr. Macpherson, in acknowledging this, said, by way of explanation, that he believed, from experiments, "that a large chamber "below the point of combustion acts on the regenerative principle." Now there is here a misuse of the word regenerative which is not confined to Mr. Macpherson, although his speech affords an opportunity for making the necessary correction. What he meant in this case is that a large chamber inside a gas-burner allows the gas to become heated. This has nothing whatever to do with regeneration, however, which is a word meaning, in the case of furnaces or gas-burners, the returning to the point of combustion of the dark and otherwise waste heat of the products of combustion. It is of the first importance, in the interest of precision of knowledge and expression, that the word should be restricted to this meaning, and not used loosely, as there is a tendency to do, in connection with any gas-burner in which there is some device for heating the air or gas. If this heating is effected at the expense of the living flame itself—whether by conduction of the heat of the flame through a metal body containing the gas before ignition, as in the case stated by Mr. Macpherson, or otherwise—the burner has no claim to be called a regenerator, as any effect it produces is not by regeneration.

THE MEETING OF THE SOUTH METROPOLITAN GAS
COMPANY—MR. BRAY APPEARS AGAIN.

THE Ordinary General Meeting of the South Metropolitan Gas Company was held on Wednesday last; and the usual report of the proceedings will be found in another column. The speech of the Chairman, Mr. George Livesey, in moving the adoption of the report, does not present much matter for comment. He had evidently read the remarks which appeared in last week's JOURNAL upon the wearisomeness of the detailed comparison of entries in new accounts with others a year old; and he most scrupulously refrained from giving occasion for similar complaint in his own case. With the single exception of the cost of coals—which, as he pointed out, were 4d. per ton cheaper—Mr. Livesey did not do any mental subtraction sums. The principal part of his speech was devoted to a

statement of the part he took in connection with the movement for the abolition of the Coal Dues; but this was only an amplification of what he said at the recent meeting of the Chartered Company. The statement respecting the organization of cookery lectures by the Company, and the immediate results of this step, was most instructive. Mr. Livesey claims that by this means the Company have succeeded in placing out 1000 additional stoves; and as a gas-rental of £5 per annum per stove is not an extravagant estimate, it follows that the Company stand to gain an increase of business from this source of not less than £5000 a year. The chief interest of the meeting, however, to those who were present was the personal attack made by Mr. George Bray upon Mr. Livesey. It is much to be regretted that Mr. Bray has not chosen earlier the opportunity afforded by these meetings for showing his rancour against Mr. Livesey. He has been seen in the room on previous occasions; and as one of the counts of his indictment of the Chairman referred to business that transpired several years ago, he might have raked the matter up at any time since he became a shareholder on April 1, 1886—and, it may be remarked in parenthesis, with equal success. He might just as well have tried his strength against Mr. Livesey here as elsewhere. On Wednesday he prefaced his stale matter with a restatement of the ridiculous fable about the East Greenwich Gas-Works sinking into the ground, which, in its absurd inflation upon the thinnest possible basis of fact, is of a piece with most of Mr. Bray's "charges." Nobody can surpass Mr. Bray in the art of blowing bubbles. Give him a drop of soapy water, and he will blow the most surprising bubbles of all sizes and shapes, and link them together so cunningly that, to his own perverted vision, they appear like a chain cable of damnable evidence. His conduct on Wednesday was characteristic to a degree. He preferred a vague "charge" against the Directors, of withholding "sound and true information" from the proprietors. When ruled out of order, he contended that he was in order. He threatened that unless he was satisfied then and there, the Directors would hear more of the matter; and he coolly ordered the Chairman when to reply to him. By no stretch of charity can it be held that his remarks were inspired by regard for the prosperity of the Company; and if he wanted to learn how such a variation upon the ordinary business of a shareholders' meeting as he provided is regarded by the proprietors generally, he had his lesson from Mr. G. Howlett and others. As we said before, however, these meetings afford him a capital opportunity for showing the spirit in which he regards Mr. Livesey; and it is to be hoped he will take the fullest advantage of them. Has he overlooked the possibility of becoming a shareholder of the Crystal Palace District Gas Company, where he would have the additional advantage of vilifying Mr. Livesey as a Director, and Mr. Magnus Ohren and Mr. Charles Gandon as respectively Secretary and Engineer of the Company? If so, we make him a present of the suggestion. Seriously, however, what an extraordinary spectacle is presented by this behaviour of Mr. Bray towards those whom he elects to distinguish by his hate! Where is there a parallel to it? Mr. Bray is one of the phenomena of the age, if he only knew it.

NORTH OF IRELAND ASSOCIATION OF GAS MANAGERS.

The First Annual Meeting of this Association, held at Lisburn last Tuesday, was in every respect a satisfactory inauguration of what we cordially hope will prove a career of increasingly useful work. The whole of the arrangements for the reception of the members were carried out by the President (Mr. E. Stears) and Mr. James Whimster, of Armagh, with the latter of whom originated the idea of forming the Association, and who has since undertaken the duties of Honorary Secretary and Treasurer. Under the direction of these two gentlemen, an attractive programme of business had been settled; and, with the exception of one item, it was completed before the members dined together as a fitting close to the day's proceedings. A visit to the works of the Lisburn Gas Company was made by most of those attending the meeting; and this enabled them to follow with interest and greater profit the account of the works given by the President in his opening address. Thereafter three highly practical papers were read—by Mr. W. B. Featherstone, of Dundalk, on the utilization of tar for various purposes upon and outside gas-works; by Mr. A. Waddell, of Newtownards, descriptive of his experience with Hislop's regenerative furnace for the heating of retorts; and by Mr. J. Robb, of Limavady, giving an account of his arrangement of retort-setting specially adapted for small works. Discussions

of a conversational character followed the reading of the papers; and the authors of them were complimented for the trouble they had taken in their preparation. It should be mentioned that consequent on the half-yearly meeting of the Cork Gas Company being fixed for the same day, Mr. T. Travers was unable to be present to read the paper he had promised on the question, "How can we best Assist our Consumers?" A strong Committee was elected to carry on the work of the Association during the coming year, with Mr. Featherstone as President; and, out of compliment to him, it was arranged to hold the next meeting at Dundalk. In closing this brief notice of the gathering (reported elsewhere to-day), we cannot but congratulate the Executive on the success that has attended their efforts to launch the Association—the healthy tone of friendliness pervading the whole of the proceedings auguring well for the future of the Society.

THE BRITISH ASSOCIATION MEETING.

The scientific world is looking forward to the forthcoming meeting of the British Association for the Advancement of Science, which is this year to be held at Bath under the presidency of Sir Frederick Bramwell, who is called by a writer in *The Times* "one of the most popular members of the Association." It is rather a remarkable thing that the climax of a successful Civil Engineer's career appears to be election to the three honourable offices of President of the Institution of Civil Engineers, Chairman of the Council of the Society of Arts, and President of the British Association, which usually follow fast on each other. This was the case with Sir William Siemens; and the experience is repeated by Sir Frederick Bramwell. No doubt Sir Frederick will be able to give the world an interesting Inaugural Address. He may not find much to say about gas, although his connection with it must have been very profitable; but he is certain to say something about his newer love, electric lighting. One feature of the meeting is expected to present unusual interest. A number of discussions have been arranged for upon specified subjects, and much expectation has been excited respecting the outcome of this experiment, which is decidedly worth trying in other scientific societies. It has of late been complained that the time allowed for the discussion of papers contributed in most of the sectional meetings of the Association has been insufficient, and it remains to be seen whether, by the device stated, discussion can be reinstated to its proper place as one of the chief attractions of a meeting of scientific authorities. It always seems a matter for regret when the time of such meetings is too much occupied with the reading of papers, many of which must be of inferior interest and value to much that a few of the audience who are condemned to silence could advance on the same subjects. It is not within our province to discuss in advance the topics that are likely to be dealt with in the various sections. It may be mentioned, however, that Lord Bramwell is to preside over the Section of Economics; and as his Lordship is known to be a determined opponent of the socialistic tendency of the age, the debates in this department of the Association bid fair to be pretty lively. Professor Foxwell is to contribute a paper on "The Tendency of Competition to Result in Monopoly," as to which the history of the gas supply of London and many other towns may be cited as potent examples likely to occur to the minds of our readers. Mr. L. L. F. R. Price is down for a paper on "The Relations of Sliding Scales to Economic Theory," which also has a familiar sound. Mr. W. H. Preece is to preside over the section devoted to Mechanical Science, and is expected to review the practical applications of electricity, with special reference to lighting. In this section Professor G. Forbes is to explain the Westinghouse system of electric lighting, for the first time in England. Altogether, if not exceptionally brilliant, or likely to be rendered remarkable by the announcement of any great discovery, the meeting bids fair to be of average interest.

GASHOLDERS WITH MODIFIED GUIDE-FRAMING.

THE Rotherhithe gasholder experiment, and the observations we made upon it, have drawn an interesting criticism from the correspondent who has chosen on previous occasions to call himself "Theory and Practice"—a *nom de plume* which fits him better than most appellations of the kind. We have nothing particular to object to in the severity of the condemnation which the critic meets out for our own remarks. So long as this class of subject is discussed with that amount of interest which leads to useful developments either of theory or practice, it is idle to cavil at expressions denoting individual differences of opinion. There is nothing like a question of strains to evoke such expressions among engineers who

habitually study these matters, as anyone may see by the correspondence columns of the general engineering periodicals. He would be a rash man who would expect to obtain a consensus of professional opinion respecting the amount and direction of the strains in a three-legged stool, and how much more diversity of doctrine may be permitted in regard to such a complicated structure as a telescopic gasholder! Our esteemed correspondent accuses us of confusing between the load upon a cantilever and the method by which the load is sustained. It is possible that, in the endeavour to be direct and simple in expressing the most obvious results of the Rotherhithe experiment, we may have erred in this way; but the impeachment does not weigh very heavily upon our conscience. When we remember how recondite the theory of beams may appear when treated *au fond* by such writers as Rankine, and how intelligible to the most ordinary capacity the principle of the lever is made by Tait and other elementary teachers who, for the immediate purpose, ignore the theory of "couples," it may perhaps be pardoned if it is sought to render the first semi-popular statement of such a novel result as that of Rotherhithe more readable and striking than profound. We have not pretended to conceal the fact that in this structure, with shortened guide-framing, the top unsupported lift is required to transmit, through its own substance, whatever overturning stresses it may have to endure to its base, instead of transferring them to a separate supporting framework. All that we were concerned to show was that this self-sustaining power can and does exist. Nobody will deny that the top lift of a holder can and generally does press against its guide-framing—or, as it might be stated, that the guide-framing does sometimes press against the holder. The question is, Is this pressure necessary to the stability of the structure? and this question the Rotherhithe experiment answers in the negative. We are left in doubt whether our correspondent really wishes to uphold what we have apparently offended him by calling the "old theory" of gasholder framing or not. This theory, as we endeavoured to define it, is that because a gasholder presses, under certain conditions, against the top of its guide-frame, therefore the latter must be carried to the full height of the holder's path. With all deference to our correspondents' objections to the way in which our observations were worded, we maintain that but for some such modification of this view as that which we have dared to distinguish as the "new theory," the practical effect would have been that guide-framing would have been carried to the full height so long as gasholders continue to be built. Our correspondent accuses us of misrepresenting the position occupied last year with reference to this point by Mr. Corbet Woodall and Mr. Foulis; but will he contend, from anything either of these eminent Engineers is reported to have said at this time, that they would have been prepared to do what Mr. Livesey has done at Rotherhithe? We repudiate the allegation that anything we remarked upon the Rotherhithe experiment was intended to upset any established principle of mechanics, and cannot find any colourable excuse for the reproach. Our critic is hardly fair, moreover, in falling as he does upon our statement (intended merely to enforce a certain view expressed in the context) respecting the ability of a gasholder that will stand in fair weather to do so in a storm. What we meant by this rather daring observation was merely to emphasize the inherent instability of such structures, the effect of which, as we argued, is much greater than the accidental overturning strain of an external force. It was a confessed exaggeration, designed to attract attention to a factor of the general problem that seemed to require to be brought into prominence. In conclusion, we may be permitted to point out that, in his haste to find fault with our observations, the critic has allowed himself to fall into something very like self-contradiction. In one place he defends the promulgation of "theories" against the incredulity of unreasoning persons; and yet he winds up by quoting a remark of Mr. George Livesey's addressed against theorizing, merely because it can be done "at a desk"—the remarkable thing being that in this particular theory Mr. Livesey himself was deeply interested, and was more than half inclined to accept it!

In order that there may be no misunderstanding as to the consumption of gas at Reading during the summer months, it should be pointed out that the "four settings of eights," which it was stated in the article in the JOURNAL last week (p. 284) were sufficient to meet the requirements of the town at the time of the writer's visit, were "through" settings, or 64 mouthpieces.

Water and Sanitary Affairs.

THE accounts attached to the report of the Thames Conservators for the past year show that the contributions from the Metropolitan Water Companies towards the revenue of the upper navigation amounted to £15,050, in addition to £1450 in aid of the lower navigation. The dividing-line between the two sections is at Staines; and the upper navigation extends to Cricklade, in Wiltshire. The Conservators state in their report that the funds provided for the maintenance of the river above Staines have hitherto been found inadequate to enable them to carry out the duties imposed upon them by Parliament; and to this fact they have frequently called attention. But they are now in a position to announce that, with a view to overcome this financial difficulty as far as possible, they have arranged with five of the Metropolitan Water Companies for these bodies to enlarge their contributions. The Conservators express their belief that the extra revenue thus obtained "will aid very materially in the maintenance of the navigation, and in securing the purity of the water supply." Perhaps the chief benefit will appertain to the navigation; for it appears by the report that, at the time this arrangement was made, the Conservators had so successfully exercised their powers as to enable them to say that, "excepting from the town of Staines, and some minor instances which are being remedied, there is practically no pollution passing into the river above the intakes of the Water Companies." So far as Staines is concerned, the Conservators have indicted the Urban Sanitary Authority in the Court of Queen's Bench. The facts are admitted; but there are points of law to be settled in the Court for Crown Cases Reserved. We are glad to find the Conservators dealing vigorously with the numerous house-boats and steam-launches on the Thames, by serving notices on the owners, and instructing their officers to keep a strict watch over these vessels, so as to detect any case of pollution therefrom. Accordingly, there is a prospect that the river will not only be kept as clean as heretofore, but will even be subject to further improvement. The precautions requisite with regard to the water supply throughout the country are adverted to in a memorandum drawn up by Dr. George Buchanan, F.R.S., and issued within the last few days by the Local Government Board. In this document there is no reference to the Metropolis; and we presume there was no intention on the part of Dr. Buchanan to include the London Water Supply in his remarks. Everyone will agree with him that "no impure water" should be drunk—understanding by impurity that which is of a "dangerous organic" character. But one or two remarks might be strained into a meaning adverse to the use of any water taken from an open river. We do not suppose this was intended as a reflection on the character of the London Water Supply; and it is to be hoped that the public mind will be in no degree disturbed on this point. The drinking supply of London, after being tested chemically, biologically, and physiologically, proves itself to be a wholesome water, and, as such, fulfils every reasonable requirement. So far as the source is concerned, that is being guarded with increasing care; while the treatment which the water undergoes before it reaches the consumer interposes what appears to be an insuperable barrier against the passage of anything hurtful. One thing has been made clear—that the Water Supply of London has undergone a remarkable degree of improvement, for the maintenance of which there is the fullest guarantee in the shape of a most rigorous supervision, official and semi-official.

If the Corporation of London are in agreement with the report which has been drawn up by the Gas and Water Committee of that body in respect to the constant supply, the attitude of the City authorities on this subject is somewhat remarkable. The Vestries of sundry City parishes have sent in petitions, asking the Corporation to notify the Water Companies that a constant supply is required. The Committee of the Corporation having conferred with the New River Company, who supply the greater part of the City, have found the Company perfectly willing to make the supply constant as soon as the premises to which it is to be given are provided with the requisite fittings. The reasonableness of this requirement is shown by a statement in the Committee's report, that there is some danger of pipes bursting when "charged with the high pressure of the constant supply." Such a casualty in a City warehouse might involve serious damage to costly goods. But the Committee have a supreme

consideration for the cost of the fittings, and are of opinion that the expense would be more than the householder would care to incur. Another apprehended difficulty is that of doing away with all the old fireplugs; rendering it necessary that the number of hydrants should be doubled. Fire-plugs will not stand high pressure, and hydrants must be substituted. But there are so many hydrants in the City already, that we should have thought a moderate addition to their number would have sufficed to take the place of the remaining fire-plugs. Moved probably by a kind of sympathetic instinct, the Committee took counsel with Mr. Archibald Dobbs, who told them "he felt very strongly that the "citizens would regret it, if the petitions in favour of a constant supply were acceded to." Why they should regret it does not appear, except on the ground of expense, which the Committee estimate as exceeding £5 per house, though it is by no means certain that this would occur in every case. Outside this pecuniary consideration, it is curious to find the Committee of the Corporation using an old argument in favour of the intermittent supply—viz., that it promotes the flushing of the drains. The Committee, "for these "and other reasons," are of opinion that it is not expedient, in the interest of the petitioners and the citizens generally, to take any steps in the direction indicated. Perhaps there are "other reasons" more cogent than those which have been published. We presume it is a matter of indifference to the New River Company whether people have a constant supply of water or one that is intermittent. But it seems rather strange that the Corporation should manifest so little zeal in bringing about a change which has been persistently urged by sanitarians and recommended in Parliament. Perhaps the City Vestries will consider the matter a little further, and will conclude to lay their case before the Local Government Board, in accordance with section 11 of the Metropolis Water Act, 1871. Or they may await the advent of the County Council, in whose deliberations superior wisdom may be found. With 52 per cent. of the houses in the Metropolis in possession of the constant supply, it seems a little singular that the City, with all its wealth, should think the cost of such a boon too great for its inhabitants to bear.

THE Commissioners of Sewers will, says *Money*, make another attempt in the coming winter to waste the ratepayers' money in introducing the electric light into the City. "The Anglo-American Brush Company are desirous," our contemporary remarks, "of offering the worthy Fathers every facility; but we fancy that the common sense of the Corporation will again stop the experiment."

At a specially-convened meeting of the Salford Town Council held last Wednesday, Mr. John Graves, who has been Town Clerk for a number of years, tendered his resignation. After some discussion, the Council (by a narrow majority) decided not to accept it; but to refer to the Finance Committee the matters with regard to which his resignation had been tendered.

It is reported that Mr. D. Ford Goddard, Assoc. M. Inst. C.E., formerly Engineer, and now one of the Directors, of the Ipswich Gas Company, intends to offer himself at the next election as a candidate for the representation, in the Liberal interest, of the borough with which his family have been associated for so many years. Mr. Goddard is already a member of the Town Council.

WE learn that Mr. John Chamberlain, who has been for the past eight years engaged at the Beckton Gas-Works, will leave England in about a month, to take the appointment of Assistant Engineer (under Mr. J. T. Wynne) at the West Melbourn station of the Metropolitan Gas Company. We understand that these works are about to be considerably extended; and that the selection of Mr. Chamberlain is due to the experience he has had at Beckton in the erection of both gas manufacturing and chemical plant.

At the meeting of the Newbury Town Council last Tuesday, the salary of the Gas Engineer and Manager (Mr. R. M. Couper) was increased by £25 per annum. The Chairman of the Gas Committee (Mr. C. Lucas), in asking the Council to sanction the advance, which he said had had the careful consideration of the Committee, he remarked that though Mr. Couper's salary was the same as that of his predecessor, the work of the undertaking had increased something like 33 per cent., and two substantial reductions had been made in the price of gas.

ACCORDING to a paragraph which appeared in the *Lancaster Gazette* last Saturday, the satisfactory results of the management of the Corporation gas undertaking in the twelve months ending June 30 last has enabled the Gas Committee to recommend another reduction, to the extent of 3d. per 1000 cubic feet, in the price of gas. Taking off the discount allowed for prompt payment, the price will stand at 2s. 3d. per 1000 feet. Our contemporary heartily congratulates the Engineer and Manager (Mr. C. Armitage, F.C.S.) on the results he has achieved, and expresses the hope that the Committee will show in some practical way their appreciation of his efforts.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 349.)

As usual at this time of year, business on the Stock Exchange is rapidly becoming more and more restricted. Last week was, on the whole, very quiet; and the general tendency in the principal departments was to reduce prices. This was partly by way of reaction from the recent rise, and partly owing to lack of support, while towards the close some degree of uneasiness regarding the aspect of Continental affairs, rather accentuated the downward tendency. It was also thought probable that the Bank-rate might have been raised further on Thursday; though, in fact, it was not. The Gas Department has been an exception to the general rule—exhibiting great firmness. Several quotations have advanced, while only one Company shows a decline. The aggregate of business done has not been large; but the Metropolitan Companies have had their full share of it. Gaslight "A" continues steadily to regain the position from which it was so unreasonably displaced on the appearance of an Electric Lighting Company's prospectus; and the quotation shows an improvement of $1\frac{1}{2}$, with business marked at 259 $\frac{1}{2}$. South Metropolitan has been moderately active, and the stocks have changed hands at good figures; the top price being repeatedly marked, though the quotation is nominally left unchanged. Commercial has been unusually busy, and shows out firm; the new stock marking a rise of 2. The Suburban and Provincial undertakings do not exhibit any change, though the reports of two of them—the Tottenham and Edmonton, and the Brighton and Hove—just issued are highly favourable. The former are enabled to reduce the price of their gas by 2d. per 1000 cubic feet for the current half year, and the latter to make a similar reduction in the coming half year. Taking these facts in connection with what we said last week about the Commercial, we believe the past half year will prove to have been a very favourable one for many Companies. Of the Foreign division, Imperial Continental are 1 better; Europeans, $\frac{1}{2}$; and Malta, $\frac{1}{4}$. The only relapse is in Alliance and Dublin. The Water Companies have been so extremely quiet as to admit of no daily record of business done in them. Quotations, however, still creep up by small degrees.

In Gas the daily operations were: Monday's business was very fair, and mostly in South Metropolitan. Tuesday was much quieter. European old rose $\frac{1}{2}$. There was renewed activity on Wednesday, especially in Gaslight "A," which was in good demand. Imperial Continental rose 1. Lambeth Water also rose 1. On Thursday, Gaslight "A" was again in request, as also Commercial; the former changing hands at higher figures than the quotation. Gaslight 4 per cent. debenture advanced 1. In Water, Kent rose 2; and East London and Chelsea, 1 each. Friday's business was more restricted, but prices rose—Commercial new advancing, 2; Gaslight "A," $1\frac{1}{2}$; European new, $\frac{1}{2}$ each; and Malta, $\frac{1}{4}$. Alliance old fell $\frac{1}{2}$; and the new, $\frac{1}{4}$. Saturday was even more than usually quiet, and two or three transactions at firm figures were all.

ELECTRIC LIGHTING MEMORANDA.

ELECTRIC LIGHTING AT THE BRITISH ASSOCIATION—TROUBLES AT LEAMINGTON—THE HISTORY OF THE ELECTRIC LIGHTING AT PADDINGTON STATION—FALSE NEWS.

As if electric lighting had not been sufficiently talked about, in proportion to the amount of work done, the scientific electricians are preparing for a grand effort at the forthcoming meeting of the British Association. The chair of the section devoted to Mechanical Science is to be occupied by Mr. W. H. Preece, the Electrician to the Post Office, who may be depended upon to say everything about electric lighting except how much has been spent upon it at St. Martin's-le-Grand, and why it has not been more successful there. The paper by Professor Forbes, upon the Westinghouse system of electric lighting as carried out in America, is looked forward to with considerable interest, although it is difficult to see what he can say about it that is fresh to readers of the electrical journals. When an example of the system is practically working in England, it may be possible to learn something more about it. Sir Frederick Bramwell, as President of the Association, will probably say something to justify the title of electrician which he has assumed of late years; and it is to be hoped, for the sake of his reputation, that in this case he will make a better job of it than in the paper on electric lighting which he read some time back before the Institution of Civil Engineers, and which gave censorious people ground for remarking that it is not every man who can take up successfully with a new trade late in life. On the whole, however, we gravely doubt whether either Sir Frederick Bramwell, Professor Forbes, or Mr. Preece will be able to tell the people of Bath much to the purpose about that system of lighting which Mr. Massingham, the ex-shoemaker, proposes to bring to their doors. It seems a great drop from Sir Frederick Bramwell and his scientific satellites to Mr. Massingham, of Bath, Taunton, and elsewhere; but we should be puzzled to state which knows most about the more important side of the subject—that which touches the pocket.

We all know that even a worm will turn at last, when too heavily trodden upon; and so Mr. Arthur Chamberlain, albeit no more resembling the lowly worm than any other gentleman of his name, has been moved to give the Town Council of Leamington "a piece of his mind." As is generally the case under such

circumstances, however, the "piece" is not a very good sample; and the giver would have done better if he had kept it to himself. The authorities of Leamington were very complaisant to Mr. Chamberlain in their earlier dealings with him, and gave him a great many facilities for displaying what he could do in the way of lighting the town by electricity. As frequently happens with local authorities and their favourites, however, length of time and mutual experiences have not tended to an increase of cordiality between the parties. Some of the Town Council have said very ugly things about the electric lighting of the streets, and this body, as a whole, have lately displayed an awkward wish to have their own way about the public lighting. Consequently, Mr. Chamberlain has become utterly disgusted with them; and he has rashly seized an opportunity for telling them so in writing. He complains that his "motives are not appreciated," and emits a long growl which cannot do the Council any harm or himself any good. The actual subject-matter of the dispute between Mr. Chamberlain and the public lighting authority of Leamington is, of course, mainly of local interest. The general lesson which promoters of new-fangled means of lighting may deduce from them is one of caution how they rush in when they find a local authority at loggerheads with the gas company. It may be taken as an axiom that a town council that cannot keep upon good terms with the gas company on account of the public lighting will seldom be found permanently amiable with electricians.

For a long time nothing has been heard of the electric lighting installation at the Paddington terminus of the Great Western Railway, which was designed by Mr. J. G. H. Gordon, for the Telegraph Construction and Maintenance Company, who, after having lighted their own factory at East Greenwich, contemplated the addition of an electric lighting department to their business, under Mr. Gordon's management. Last week the *Electrical Review* published a brief history of this experiment, with which the Telegraph Construction Company began and ended their electric lighting aspirations. We are therein told, what we always suspected—that the Company had enough of electric lighting in this, their first contract, and that they "suddenly closed the electric lighting department, dispensed with the services of the Manager, and prematurely closed their engagement with the Great Western Railway Company." Not a word of all this has even been allowed to transpire at the ordinary general meetings of the Company; and the proprietors are therefore in ignorance respecting the amount of money lost by this unfortunate contract. Mr. Gordon figures prominently in connection with the Metropolitan Electric Lighting Company, which is very dubiously regarded by our contemporary. They freely admit that there has been something retarding the advancement of electric lighting which electricians have not yet been brought to acknowledge. We always say simply that there is "no money" in the business, as it must be carried on under the conditions prevailing in Great Britain; and it would probably be found, upon investigation, that there is not much difference of opinion on this point between the *Electrical Review* and ourselves, if the whole truth were revealed.

Having just said a good word for the honesty of purpose of the conductors of the *Electrical Review*, it is rather a pity that we must follow this up by a protest against the same journal of disseminating false intelligence. Yet in the same issue in which the history of the Paddington electric lighting experiment is truly told, there appears an altogether misleading report respecting the circumstances of electric lighting in Paris. We are told that "the use of electricity in every-day life in Paris is becoming more and more manifest." This may or may not be true in a general way; but the writer goes on to assert that the principal thoroughfares of the French capital will soon be lighted by electricity, but that the great stumbling-block is the city Gas Company, which is working tooth and nail to resist the innovation. Its losses have already been considerable, and the Directors are doing all in their power to retain custom by constantly lowering the price of gas. The shops which still burn gas are in an insignificant minority." It would be difficult to condense more blunders into as many words. It must suffice, by way of correction, however, to remark that the Paris Gas Company are established upon the basis of a concession under which a large proportion of the profits are divisible between the shareholders and the Municipality, and that accordingly the price of gas has not been reduced by a centime for more than thirty years. It might have been thought that no resident in Paris could have remained in ignorance of the troubles which the Gas Company have had with their customers upon this very point. Our contemporary has been egregiously misled in this matter, as our readers scarcely require to be told.

ONE of the largest firms of producers of gas coal in Durham have just intimated their intention to raise the price of their coal to 7s. 6d. per ton, less 2½ per cent.; and it is expected that others will follow the same course. For best gas coal the demand is very large; and it is anticipated that there will be higher prices known this winter, now that an advance is obtainable so early in the autumn.

THE gas industry in France has lately lost an able member in the person of M. Meizel, who for a long time filled the position of Chief Engineer of the St. Etienne Gas Company. M. Meizel was associated with M. Cadel in carrying out the series of experiments in hot condensation, of which an account appeared in the *JOURNAL* a few years since; and his name has occasionally come before our readers in connection with improvements in gas manufacturing appliances.

SACCHARINE AS A SUBSTITUTE FOR SUGAR.

ACCORDING to reports which have reached us from various sources, the substitution of saccharine—the recently discovered sweetening material produced from coal tar—for sugar is not attended with the advantages which were at first claimed for it. Mr. J. Michels, writing lately in *Health*, stated that he had been using saccharine instead of sugar for domestic purposes for about a month, and had found it difficult to dissolve, even in boiling water, although soda was added, and other means were taken according to formula, for making a perfect solution. Mr. Michels says this trouble has been spoken of by all who have made use of the substance. Saccharine is not altogether odourless or tasteless; but in use it does not impart any particular flavour, and he found its sweetening property all that could be desired. He thought it convenient to make a solution of sufficient strength that a teaspoonful would sweeten a breakfast cup of tea. Using it in this manner, tests were made in many ways—such as making lemonade, custards, puddings, mixing with acid fruits, and various kinds of domestic cooking. In all such cases the saccharine imparted an agreeable sweetness, but did no more than counteract or neutralize acidity. Now, it is well known that sugar not only has a sweetening property, but seems to be possessed of a power of bringing out an increased flavour of the substance it sweetens—in other words, the flavour is intensified. Mr. Michels found that the use of saccharine, on the contrary, appeared to deaden the flavour of the substance sweetened; and this is a great disadvantage. Attention has also to be drawn to the fact that sugar is a food—a quality not possessed by saccharine, which passes through the human body unaltered and never digested, affording no nutrition to those who take it. For these reasons it can never replace sugar as an article of diet, however cheaply it may be produced. It, however, will be a blessing to those persons afflicted with diseases in which the use of sugar is prohibited. Mr. Michels does not recommend the unlimited use of saccharine; not being altogether sure of its inert property while passing through the human system. He therefore advises those who are prohibited from taking sugar to use saccharine very sparingly, and only when necessary to counteract great acidity. He trusts that the day is far distant when saccharine will be produced at a cheap rate, as it will in that case be largely used as an adulterant in the place of sugar; and then it will be very difficult indeed for the public to distinguish the difference.

The Council of Hygiene and Salubrity of the Seine have definitely settled, on the basis of the reports of experts appointed by them, the certainty of the unwholesomeness of saccharine as a sweetener. These gentlemen stated that the sensation of sweetness produced by saccharine on the tongue lasts much longer than that produced by ordinary sugar; but it is much less agreeable, inasmuch as it leaves an after-taste of bitter almonds and a dryness of the throat. It is quite possible, they say, that to its method of preparation, and the impurities which cannot be entirely separated from it, may be attributed the ill-effects resulting from the use of saccharine. But it is equally possible that it is dangerous in itself, by reason of its intrinsic properties. At all events, its antiseptic qualities, by which the fermentation of substances with which it amalgamates is arrested, may become a positive danger. For the proper digestion of food, it is absolutely necessary that the action of the gastric juices should not be paralyzed; and it is precisely the contrary effect which is produced by the use of saccharine. Although this substance is supposed to be thrown off almost in the same proportion as it is taken, in cases of organic derangement it is liable to accumulate and produce unhealthy symptoms, such as indigestion, cramp, and general discomfort. Admitting even that saccharine is absolutely inoffensive from a hygienic point of view, it must be borne in mind that it is at a disadvantage compared with the ordinary cane or beetroot sugar, inasmuch as it has no nourishing properties. A curious fact about saccharine is that insects seem to have a positive dislike to it. In a pastrycook's shop, where a number of tarts and cakes had been sprinkled with saccharine, it was observed that a wasp and the inevitable flies carefully avoided settling on them—the wasp especially, for on a cake sprinkled with saccharine being purposely put in its way, it displayed a great amount of irritation.

In a communication to the French Academy of Medicine, Dr. Worms states that of several patients who made use of saccharine by his advice, all but one were soon compelled to give it up, on account of the occurrence of dyspeptic symptoms, nausea, loss of appetite, &c. It is usually not until after the substance has been taken for from 10 to 15 days that it manifests its evil influence; and it then appears to accumulate in the system. It has been computed by Professor Salkowski that the quantity of saccharine which an ordinary man in a condition of sound health and of medium strength may take daily with impunity is certainly not more than 1½ grains.

As to the detection of saccharine when mixed with other matters, Mr. D. Lindo, writing in the *Chemical News*, says it would seldom be possible to detect it, unless it was first isolated in a state of at least tolerable purity. Chemical tests that can be easily applied for its identification in this condition are probably known, and may have been published; but he has not met with any, except the production of salicylic acid from the compound by fusing it with potash or soda. He has failed as yet to obtain a characteristic reaction for the substance in solution. The following test, which must be applied to the solid body, is believed to be original. It consists in evaporating to dryness on a water-bath, the saccharine mixed with an excess of nitric acid. A fragment of caustic potash (not too small) is then added, and a drop or two of water, without

removing the dish from the bath. Colour is at once developed, and if the dish is inclined, streaks of colour—blue, violet, purple, and red—flow into the caustic; the reaction is very fine, and is still more beautiful if 50 per cent. alcohol is added to the potash instead of pure water. The test, however, is not extremely delicate; and 0.5 milligramme of saccharine in the solid state is about the smallest quantity that will give definite results. Heat is necessary to develop the colours, and apparently a large excess of alkali. Soda does not appear to act as well as potash. Colour reactions obtained with coal-tar products must, Mr. Lindo adds, always be suspected of not being characteristic.

THE GLASGOW INTERNATIONAL EXHIBITION.

EIGHTH ARTICLE.

THROUGHOUT all the civilized world, the Saracen Foundry of Glasgow is well known as being the place where the famous "Macfarlane's castings" are produced, more especially sanitary and rainwater goods and art castings in almost endless variety. It was therefore but natural to suppose that Messrs. W. Macfarlane and Co., the proprietors of that great foundry establishment, should take a prominent place in the Glasgow Exhibition, by way of upholding the fame and reputation of the important industrial district of which Glasgow is the centre. The position given to the firm is a very decided acknowledgment of their eminence in the production of high-class foundry goods in a variety of classes or departments. It is not necessary that we should enlarge upon the beauty and general excellence of the constructive and decorative ironwork shown by them; but our reference to this extensive collection is more with the view of directing attention to the examples of lamp-pillars, brackets, pendants, &c., for lighting by gas in public thoroughfares, railway stations, halls, churches, warehouses, &c. Most of these productions of the art foundry are well worthy of study. One of the lamp pillars—a massive and very beautiful piece of ironwork—is surmounted by a group of five lanterns, all in frameworks of castings formed of elegant tracery and foliar details. Another combination consists of a handsome pillar, surmounted by a main central lantern and by two side-arm lanterns—similar to pillars which have been erected at many street crossings in London. Others are examples of pillars which have been fitted at various banks and other public buildings in Glasgow. Altogether, Messrs. Macfarlane and Co. have acquitted themselves well in their display of ornamental cast-iron manufactures; and for their lamp-pillars, &c., they deserve very great credit.

There are several stands in the Machinery Court proper which are specially deserving of some attention at our hands. One of these is the collection of instruments shown by Murrie's Engineering Company, of Glasgow. The instruments referred to are chiefly pyrometers and thermometers, which have a very extensive range of usefulness, as they are capable of indicating (continuously and accurately) any degree of temperature between 50° below to 2000° above zero Fahr. They are constructed throughout of specially prepared homogeneous steel, and are subjected to severe continued tests, so as to ensure accuracy in graduation; and they indicate the degree of heat with unvarying precision. The instruments here shown are coated with nickel, copper, or platinum, depending on the purpose to which they are to be applied. It may be mentioned that these instruments are made in groups suited for various classes of operations where the temperatures employed are within certain well-defined limits. For example, Nos. 10 and 11 are specially designed for ammonia-stills, &c.; the ranges of temperature being, respectively, from 150° to 250° Fahr., and from 220° to 350° Fahr. Another group are intended for indicating the temperatures employed in tar-distilling and similar operations. Nos. 24 to 28 are suitable for indicating temperatures ranging from 400° up to 2000° Fahr.—such temperatures as are reached in gas, shale, and other retorts. Then, lastly, there are instruments designed for testing the temperature of regenerator furnaces, &c. Gas managers, tar and ammonia distillers, &c., who have used these instruments speak very highly of them, as their indications are exceedingly trustworthy. There is also shown at this stand an improved duplex pump, such as may be used for pumping tar, oil, ammoniacal liquor, &c. In this piece of apparatus there are two slide-valve steam cylinders, and two double-acting pumps; each pump and its steam cylinder being so arranged by the side of, and connected with the other, that the steam-valve of each is operated by the steam-piston of the other. In each case the cylinder has a gun-metal liner. Gas managers, equally with other steam-users, are deeply interested in the correct working of the boilers under their charge; and consequently a perfect low-water alarm can scarcely fail to be of advantage to them. At the same stand an alarm is exhibited which is exceedingly simple in its construction, and which can be tested at any time without interfering with the working of the boiler. It consists of a chamber or hollow sphere, placed outside the boiler, above the highest water-level. A tube or channel leads from the chamber to the interior of the boiler; the nose of the tube terminating at the lowest water-level. The outside chamber is fitted with a float, which, as it rises and falls, operates a valve on the higher end of the chamber, to which a steam-whistle is fitted. When the nose of the dip-pipe is immersed in the water, the steam-pressure, acting on the surface of the water in the boiler, maintains the outside chamber full of water; and, in consequence, keeps the float in its highest position—thus closing the outlet-valve. On the nose of the dip-pipe being uncovered, the water falls into the boiler, and the float descends; thereby opening the valve and permitting the steam to escape and sound the whistle.

There are various stands in the Machinery Court at which pumps are shown of kinds suitable for use about gas-works, for pumping tar, ammoniacal liquor, &c., or for filling and emptying gasholder tanks, circulating water through condensers, &c. In this connection attention should be directed to the display of pumping machinery at the stand of the Pulsometer Engineering Company, and more especially to their "Deane" double-plunger, their "Cyclic," and their "Pulsometer" pumps.

At the stand occupied by Messrs. Fielding and Platt, of Gloucester, there are shown various examples of that firm's patent duplex pumping-engines, suitable for many purposes, including the pumping of gas tar, ammoniacal liquor, &c. The distinctive feature of these pumps lies in the fact that the steam cycles are controlled by means of a single-slide valve. By this arrangement it is said the parts required are greatly simplified and reduced in number, with a corresponding reduction in wear and tear, and in the amount of attention needed. It is also claimed that, as the valve is moved in two directions, one transverse to the other, its surfaces always remain in a perfectly steam-tight condition; and consequently they never require re-facing or renewal of any kind. An excellent display of pumping machinery is likewise made at the stand of Messrs. S. Owens and Co., of London, who are well known for their gas exhausters, gas-valves, &c. A prominent feature of the goods which they display is the collection of Blake's steam-pumps, such as are installed in and about many gas and water works, both at home and abroad. Similar apparatus to that which we have referred to in this article will also be found in other parts of the exhibition.

Notes.

ANOTHER COKE-BREAKER.

The accompanying illustrations, which are taken from a recent number of the *Journal des Usines à Gaz*, show a new form of coke-breaker devised by MM. Bréant Fils, in which centrifugal

force is directly applied to effect the desired object. The apparatus consists of a cast-iron framework supporting a hopper A, from which the broken coke is discharged, and a cylindrical body, furnished inside with angular projections, as shown. This cylinder bears the receptacle B, into which the large coke is thrown. In the centre of the cylinder there is fitted a "projector" C, which turns with a rapid horizontal movement—the speed depending upon the hardness of the material to be broken. This projector is fixed at the extremity of a vertical shaft, which receives its motion from a horizontal shaft (through the medium of the cog-wheels D, fixed at suitable angles) worked by the driving-wheel at the end. The action of the machine is extremely simple. The large coke, on being shot into the hopper B, falls into the space below, where it is attacked by the projector, thrown with considerable force against the serrated inner surface of the cylinder, and broken by the violence of the shock. The outlets of the hoppers are so arranged that, however large may be the coke, and however rapidly the machine may be fed, the lower hopper can never become obstructed. Consequently, friction of the pieces of coke one against another is avoided, with a resulting diminution in the production of breeze and dust. The constituent parts of the machine are of a simple character, strong, and durable. It has been tried in the presence of a number of gas engineers, with the result (according to our French contemporary) that a loss of only 5 to 6 per

cent. was shown, with an addition of 4 to 5 per cent. of dust. So that, after breaking and sifting the coke, a maximum loss of only 8 to 10 per cent. is sustained.

REDUCTION OF GAS VOLUMES TO NORMAL TEMPERATURE AND PRESSURE.

Herr Lunge has devised an apparatus for reducing gas volumes to normal temperature and pressure. It has been illustrated in the *Chemiker Zeitung*; and an abstract of the description was lately given in the *Journal of the Society of Chemical Industry*. Both Herr Lunge and Herr Winkler have already shown how a nitrometer may be used for bringing gas volumes to normal pressure and temperature. The volume of gas to be reduced is compared with the volume taken up by 100 c.c. of gas, which are permanently enclosed in a nitrometer at 0° C. and 760 mm. pressure. The quotient forms the factor by which the gas volume to be reduced has to be divided. Multiplication has been found more convenient in practice; and by substituting for this factor its reciprocal figure, multiplication takes the place of division. The author advocates engraving on the apparatus the reciprocal figures, and publishes a small table for the guidance of the manufacturer of such apparatus.

WATER POWER IN THE UNITED STATES.

The American Statistical Association has, says *Industries*, published a paper on the subject of the water power employed in the United States for manufacturing purposes. In 1880 there were in use 55,404 water-wheels and turbines, giving a total power of 1,225,379-horse power; this being 35·93 per cent. of the total power employed in the country for manufacturing purposes. Professor G. F. Swain, who has drawn up the paper, states that the value of water power, like that of any other commodity, is governed by the law of supply and demand, and depends upon a multitude of circumstances; but inasmuch as water power could not, in any part of the country, be replaced by steam power at a less annual expense than about £4 per net effective horse power, the annual value of the utilized water power would, on this basis, amount to nearly £5,000,000. As regards the distribution of water-power among the more important industries, the largest proportion—70·70 per cent.—is found in the case of paper-mills. Of the total power used in flour and grist mills, about 61 per cent. is water power. This finds its explanation in the fact that the majority of these mills are small, and for local use only. The raw material and the finished article are respectively produced and consumed in the immediate neighbourhood, and convenience of transport enters little into the question; so that water power, on account of its intrinsic cheapness, is preferred. In the manufacture of cotton and woollen goods, one-half the total power is water power; and in the case of worsted goods, the proportion of water power is still above the average for the entire country. On the other hand, the proportion of water power employed in the manufacture of boots and shoes, and of iron and steel, is very insignificant. In the former case this is explained by the small amount of power used per establishment, the limited use of water for purposes of manufacture, and the almost forced location in certain places; and in the case of iron and steel, questions of location and ease of transport explain the small proportion of water power.

SOUTH-WESTERN GAS ASSOCIATION OF THE UNITED STATES.—A short time ago several gas managers located in Texas discussed the subject of forming an Association of Gas Engineers in that State; and the project was so favourably received that a meeting was called, and the preliminaries arranged. The new organization is called the South-Western Association; and its object is to be the professional improvement of its members, and the advancement of gas engineering in its several branches. Colonel J. P. Smith (of Fort Worth) has been chosen as temporary Chairman; and Mr. C. P. Russell (of Houston) will discharge the secretarial duties. The last number of the *American Gaslight Journal* contains the articles of constitution of the new Association, which we trust may have a successful career.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.—The seventy-fifth quarterly meeting of this Institution, which will be held at Doncaster next Saturday, will be a specially interesting one. The Council Chamber at the Town Hall has been kindly placed at the disposal of the members by his Worship the Mayor (Alderman Wainwright); and there, after a luncheon at the Elephant Hotel, the business will be transacted, under the presidency of Mr. T. Duxbury, of Darwen. Two gentlemen—Mr. T. Settle, Manager of the New Mill Gas-Works, near Huddersfield, and Mr. W. Drewry, Manager of the Cleethorpes Gas-Works—will be proposed as members. The discussion of Mr. Dalglish's paper on "Oil and other Illuminants, and their Effect on the Consumption of Gas," read at the meeting of the Institution in December last, and given in the *JOURNAL* for the 20th of that month (p. 1091), will doubtless bring out some valuable facts; but the attention of the members will be chiefly directed to a paper to be read by Mr. T. Newbighing, C.E., on "Gasholders without Upper Guide-Framing." With the author's well-known thoroughness in all he undertakes, he has had a diagram and models of holders prepared to illustrate his remarks. At the close of the business the members will pay a visit to the ruins of Conisbro' Castle; and on their return take tea together. Although we are now in the holiday season, the programme issued for the meeting by Mr. Harrison Veevers, the Honorary Secretary, is by no means of this character.

Communicated Article.

MANAGEMENT OF GAS-WORKS EMPLOYEES. CONCLUDING ARTICLE.

We have last of all to consider the course to be adopted in cases of accident or sickness. Government has already taken the former in hand by means of the Employers Liability Act, by which the responsibility for accidents during working operations is chiefly thrown upon the employers of labour. Gas-works are fairly safe places, and enjoy a considerable amount of freedom from accidents or casualties. Several respectable Insurance Offices have, therefore, found it worth while to issue policies covering all liability under the Act at remarkably low premiums, which afford but an inconsiderable addition to the wages sheet. It is a very general custom to take advantage of this opportunity of avoiding risk of being "let in" for heavy expenses and damages. Government also offers some assistance to employers by sending round inspectors to see that exposed cog-wheels, cranks, or other moving parts are properly fenced in, and other precautions taken with a view of reducing risk of accident as low as possible. All men are, of course, liable to sickness, and at some gas-works considerable latitude is observed with regard to sick pay; but there are several reasons in favour of a rigid rule, enforcing the payment of each man only for the time actually worked. It is difficult, when once the practice of allowing sick pay at full wages (by continuing the wages during a man's absence on account of illness) is established, to know where to draw the line. Perhaps things have gone on quietly for some years, when suddenly a regular epidemic of "absent on account of sickness" sets in, which will have a marked effect upon the wages sheet. A coincidence between the sick times and the periods of local holidays or rejoicings will also be noticeable. If one man is allowed a week's absence on full pay on account of sickness, it is difficult to refuse ten days similar privilege to a second, or a fortnight to a third. Where this practice has obtained, the first opportunity that offers, such as a rise of wages, the introduction of Sunday stopping, or any other privilege, may be taken advantage of to put an end to it. And when this is done, the result may, as was once actually observed by a working man, prove that the stoppage of sick pay is "the best doctor that ever came into the place." It must also be remembered that there are several sick clubs in every town; and a member of one of these, if allowed sick leave on full pay, may draw his allowance from the club as well, and thus derive an actual profit of 50 per cent. or more on his ordinary day wages, for every day's absence.

If the number of men employed on the works is large enough, it is a good plan to establish a sick or provident fund for the employees, or, rather, to encourage and assist them in forming one. Whilst declining any actual responsibility in the establishment or management of the same, the manager may countenance it in every possible way, such as by allowing the use of a room on the works for the business meetings, taking the chair at the annual gathering, &c. Apart from the question of policy, it is simply a matter of duty that the employers of labour should take some interest in the well-being of those whom they employ; and therefore any scheme which renders the men more provident in their habits, or in any way tends to their welfare—physically, mentally, morally, or spiritually—should be heartily encouraged. Much can be done in the way of providing a comfortable room for meals, a bath room, and even a reading room for the men. If the works are small and employ only a few hands, the manager may be of service in getting information as to the safest and most reliable provident clubs in the neighbourhood, and in other ways.

What is to be done with the old servants, worn out in the company's service, is frequently a troublesome question. In many instances the Act of Parliament contains no provision for such cases—a striking contrast to the rules in many branches of the public service. The man who has devoted the best years of his life to the service of the Company certainly has a right to complain if he is cast off in his old age, when unable to take up any other remunerative occupation; for it is idle to pretend that the wages paid, either to the lowest or the highest, are such as to leave a margin for the accumulation of an independency, after paying the daily expenses of living, &c. Therefore, there can be no question as to the justice of establishing superannuation funds. In cases of amalgamation, the principle of awarding an adequate compensation for loss of office, even to men in the prime of life, has been recognized and sanctioned by Parliament; how much more is it just to award compensation when the loss of office is rendered imperative by the inexorable laws of nature? Particularly in regard to the retort-house and the lamp-lighting, does this apply, as these duties require a man to be in full possession of activity and energy. There is usually something to be done in the way of finding positions—such as store-keeper, gatekeeper, valvesman, &c.—for old and trusty servants who have lost the activity of youth, or they may be put on as general utility men, or employed in what, by a curious perversion of actual fact, is usually called "running" errands. But old servants ought not to be left to the tender mercies of chance; there should be a recognized scheme for meeting their case. The many advantages afforded to the manager by the general knowledge of the existence of such a scheme, are obvious. Once a man has remained a few years in the employ of the Company, there is the prospect of "losing his pension" by bad behaviour or dereliction, on his part. It is a great mistake to allow old men to remain on the works a day after they are really unable to discharge the duties they undertake, or to take their fair share with the rest of the gang.

They expect little indulgences in the way of unpunctuality, sitting down to have a smoke now and then, &c., which perhaps cannot be refused to them with a good grace, but which also can never be tolerated if good discipline and method are to be maintained amongst the men. The better plan, in the absence of a proper fund, is to meet such cases by means of an allowance, or gratuity, or any other form of compensation that will be allowed by the auditors. In some works a regular superannuation fund for the benefit of *employés* forms one of the features of the provident club; and it is scarcely necessary to add that such a fund should receive liberal support from the company.

Technical Record.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

OFFICIAL REPORT OF THE PROCEEDINGS AT THE ANNUAL MEETING IN GLASGOW.

The Twenty-Seventh Annual General Meeting of the members of the North British Association of Gas Managers was held on Thursday, July 26, 1888, in the Hall of the Philosophical Society, Bath Street, Glasgow—the PRESIDENT (Mr. David Terrace, of Dawsholm, Glasgow) in the chair. There was a large attendance.

REPORT OF THE COMMITTEE.

The SECRETARY (Mr. R. S. Carlow, of Arbroath) read the annual report of the Committee, as follows:—

The Committee now presents its fourth annual report in the form agreed on at the 1885 meeting; and the following statement gives a general outline of the business done, with some notes that may be interesting.

The property belonging to the Association—consisting of the business books, reports for past years, &c., as per list recorded in the minute-book, pp. 308–309—was handed over to the Secretary, Mr. Robert S. Carlow, who was appointed at the last annual meeting.

The remit "On the Best Standard Burner for Scotch Gas" has been under the consideration of the Committee; and it was resolved to place the results of testing of burners in the hands of Mr. George R. Hislop, the Convener of the Sub-Committee on this question. Mr. Hislop kindly undertook this work; and to-day we are to have a paper embracing this interesting subject. The Committee's work in this matter may now fairly be considered at an end; and it is now for you to relieve the said Committee, with thanks.

The Research Fund has been contributed to by 50 companies.

In reference to the remit to Mr. William Young, along with a Special Sub-Committee, to investigate into the question of purification in closed vessels, the Committee regret that arrangements could not be completed in time to allow of a report being presented to this meeting; and recommend that the same Special Sub-Committee be requested to continue in office for another year. Proposals or suggestions from the members would be considered by the Committee, and reported on in due time.

The Benevolent Fund has been drawn on to the extent of £20 during the year.

The "Statistical Report, 1887," was compiled and issued to all the members, as well as to those who gave the necessary information.

The "Annual Report of Proceedings, 1887," was published and sent to each member of the Association, according to the rules. It contained the President's address, papers and discussions thereon, a list of the Past-Presidents, new members admitted, names of members of Committee, rules, &c.

It has again been considered advisable to postpone taking definite action in reference to the Murdoch Memorial. The amount at the credit of the fund is now £287. The Sub-Committee are endeavouring to raise further subscriptions, and fully trust that by another year the present sum will be considerably augmented.

In reference to the generous offer of Mr. Robb, consisting of bound volumes of the JOURNAL OF GAS LIGHTING, &c., the Committee regret that, as one of the conditions of the gift cannot be complied with—viz., having a "home" for their reception in Glasgow or Edinburgh—they very unwillingly decline the proposed addition to its property.

It is very gratifying that the membership of the Association is still increasing; thus showing that it is accomplishing the end for which it was originated.

The report was unanimously adopted.

THE ROLL OF THE ASSOCIATION.

The SECRETARY next read extracts from the minutes of the Committee meeting held prior to the general meeting. They showed that the following gentlemen had ceased (by resignation or otherwise) to be connected with the Association:—Ordinary members—Messrs. J. Adamson, Anstruther; A. Dougall, Hull; J. Gibb, Armagh; J. Burden; J. Morton, Muirkirk; P. Blair; and J. Stiven. Extraordinary members—Messrs. R. Brown, Lanemark (deceased); and C. T. Grant, Glasgow. The members of the Association number 166 ordinary members, 57 extraordinary members, 12 associates, and 4 honorary members; but deducting those resigning, &c., the numbers respectively are 159, 55, 10, and 4—total, 228. Add to these 10 ordinary, 3 extraordinary, and 4 associate members applying for admission (as per following list), there is a total of 245 members, including 4 honorary members.

ADMISSION OF NEW MEMBERS.

The SECRETARY also submitted applications from the following gentlemen, who were admitted:—

ORDINARY MEMBERS.

Ballantyne, J.	Gas-Works, Rothesay.
* Bell, A.	" " Peebles.
Boyd, T.	" " Lennoxtown.
Chayne, D.	" " Mountain Ash.
Donaldson, J.	" " Lochwinnoch.
Laing, W.	" " Dysart.
* McDonald, J.	" " Denny.
* Mitchell, D.	" " Newbattle, Edinburgh.
Ross, G.	" " Stonehaven.
Walker, A. B.	" " Spittal, Berwick-on-Tweed.

* Transferred from Associate List.

EXTRAORDINARY MEMBERS.

Brown, T. M.	Gas-Works, Lanemark.
McCrae, A. B.	" " Monifieth.
Morrison, J.	" " Dalkeith.

ASSOCIATES.

Cameron, J., Jun.	Gas-Works, Tradeston, Glasgow.
Edwards, W. A.	" " Brechin.
Robertson, H.	" " Broughty Ferry.
Ruxton, W. M.	" " Arbroath.

AUDITOR'S REPORT.

Mr. D. B. PEEBLES (Edinburgh), the Auditor, in submitting the accounts, said, as there were a good many details which would appear in the annual report, he would confine himself to giving a general outline of the financial position of the Association. In the General Fund the charge amounted to £163 11s. 10d.; and there was a balance of £12 14s. 10d. due to the Treasurer. So that there was no bank account in connection with the fund. With regard to the Benevolent Fund, there was a balance of £150 at the bank. There had been several sums paid to different persons whose cases were brought under the notice of the Association. The charge there was £200 14s. 10d., which was balanced by the discharge; leaving, as he had said, a balance of £150 at the credit of the fund. Then there was the Research and Investigation Fund. The charge was £83 18s. 9d.; the cash in the Treasurer's hands, £3 1s. 5d.; and the balance in the bank, £46 10s. He concluded by congratulating the members on their choice of a Secretary, as the books were clearly kept, and all the accounts properly vouched.

The PRESIDENT: I presume these accounts meet your approval. It appears that our funds are in a healthy state; for, although there is a slight deficit in the General Fund, I am sure it will be more than made up this year. Mr. Peebles deserves our hearty thanks for the trouble he takes in auditing our accounts from year to year.

Mr. PEEBLES, in acknowledging the compliment, assured the members that the work was a "labour of love" to him.

PRESIDENT'S ADDRESS.

The PRESIDENT then delivered his Inaugural Address, which was given in the JOURNAL for the 31st ult. (p. 204).

Mr. A. MACPHERSON (Kirkcaldy) said he was sure the members had all listened with very great interest to the President, and they were deeply indebted to him for his instructive address, in which he has most completely refuted the assertion that gas engineering has made little or no progress during the past 20 or 30 years. Great benefit had been conferred on gas consumers by the improvement in burners, for instance; and if the general body of the consumers paid more attention to this matter, they would save their pockets to a large extent. He proposed a vote of thanks to the President for his excellent address.

Mr. W. KEY (Tradeston, Glasgow) seconded the proposition, which was unanimously adopted.

The PRESIDENT having expressed his thanks to the members for the compliment they had paid him, the reading of papers was proceeded with.

MR. HISLOP'S PAPER.

The first paper was on "Gas-Burners for Photometrical Purposes" (being the remit of the Committee on the best standard burner for Scotch gas), by Mr. G. R. Hislop, of Paisley. It was given in the JOURNAL for the 31st ult. (p. 205); and it led to the following

Discussion.

The PRESIDENT: I am sure we have all listened with great pleasure and profit to Mr. Hislop's paper. I should like him to tell us whether, when referring to the angles, the 30° meant off the vertical or off the horizontal.

Mr. HISLOP: Off the vertical line.

The PRESIDENT: It is important to know that, because you can read 45° either way; but you do not know whether the sharpness of 30° is one way or another.

Mr. W. FOULIS (Glasgow): I have been very much pleased with Mr. Hislop's paper. The experiments he has carried out are altogether novel—at all events, I have never seen any showing the effect of the different angles at which the holes are drilled in a burner. It could scarcely have been anticipated that, in burning the same quantity of gas at the same pressure, the results would have been so different as Mr. Hislop's tables indicate, according to the angles of the holes. The information is very important; and, amongst other things, it shows that when statements are made respecting the various qualities of gas, it is highly necessary to know the conditions under which the gas is being burned. It also shows how important it is that consumers should attend to getting proper burners, so as to obtain the fullest value from the gas. I have no doubt that some of the burners which Mr. Hislop used were consuming gas in a way which, under ordinary circumstances, would not be objected to. It shows that those who are in charge of gas-works should endeavour to arrange, as far as possible, that consumers should have supplied to them burners which are the proper ones to use for the quality of gas that is being manufactured.

Mr. D. B. PEEBLES (Edinburgh): I should like to have had an opportunity of reading Mr. Hislop's paper before coming to the meeting, because I consider that the author has brought before us an altogether novel element. I do not think the angle of the apertures in gas-burners has ever been thoroughly considered in connection with the development of the illuminating power of the

gas consumed. Long ago Mr. Stewart, of Greenock, called attention to the necessity for having burners of different sizes with certain pressures. Every burner, like every man, has its idiosyncrasy. With burners of the same size, and having the same holes, you will, by the alteration of pressure, so develop the illuminating power as to make the difference very perceptible, even with the same class of burner. I wish Mr. Hislop, while experimenting with the burners, had given the results at different pressures. This might have produced some slight difference in the flames. It is a clearly ascertained fact that every burner has a particular pressure which will bring out the greatest illuminating power of the gas being consumed. Mr. Hislop has opened up an excellent field of inquiry, which will doubtless lead to some practical result in the construction of burners. In showing off a burner, one man will hold his hand behind the flame, and say "See how beautiful." But it is the white hand that helps the flame. Another holds up a newspaper, and says "See how transparent and beautiful; you could read through it." We hear such statements made to consumers, and they are led astray by them. Anything emanating from such a body as this, and from such a man as Mr. Hislop, will carry great weight amongst consumers. This is one of the most important subjects the Association could take up, because there is no doubt of the enormous waste caused by bad burners.

Mr. W. KEY (Tradeston, Glasgow): I understood that Mr. Hislop used iron burners; and I have to ask whether he tried burners of a larger diameter at the same angles, because I think the internal diameter has a great deal to do with the development of the illuminating power of the gas at the point of combustion. The ordinary iron burner has only a small internal bore. Mr. Bray's burner has at least double or treble the area; and the "Special" burner is still larger. I think the fact of the gas having to travel through the tube before it reaches the orifice at different angles has something to do with preparing it to be ignited and consuming the hydrocarbons. It is quite true, as Mr. Hislop has said, that gas managers and the public have been slow to develop in burners the highest possible illuminating power of the gas. Our President has told us that, by our present method of testing, 7-candle gas can be increased by the "London" Argand to 14-candle, and by a regenerative lamp to 28-candle power. This proves to my mind that there is something wrong, and that Mr. Hislop is justified in saying we ought to test gas with the best burner that can be obtained. He well deserves the thanks of the members. It is a credit to the Association to have a gentleman coming forward and discussing the effect of different angles on illuminating power; and if he were to add to this the various diameters of the burners, it would be something still further for us to reflect upon.

Mr. D. M. NELSON (Glasgow): For scientific purposes, I think every one will admit that Mr. Hislop's paper is pre-eminently excellent. The difficulty I see about it is that all the tests have been made with iron burners, which are now almost out of existence for ordinary use.

Mr. A. MACPHERSON (Kirkcaldy): Mr. Hislop's paper is altogether of such a novel character, that one feels it to be necessary to have some time to study it in order to do it justice. I am sure Mr. Hislop will feel that if we do not discuss it in the way in which we deal with some other papers on matters with which we are more conversant, it is because the subject is rather beyond our reach until we have had some further time for consideration. What Mr. Hislop has shown us in these tables should set us all thinking; and I trust that burner makers and Mr. Peebles (who is so well qualified to deal with the subject) will set to work and produce burners suited for all the various qualities of gas, and bored at the proper angles. There is a great deal of truth in what Mr. Key has said about the size of the burner immediately below the point of consumption. I believe, from experiments, that a large chamber just below the point of combustion acts on the regenerative principle. The gas is heated, and the carbon is raised to a higher temperature before actual combustion takes place; and being thus brought to the highest state of incandescence, a greater amount of light is obtained than would otherwise be produced. If you send a stream of gas through a narrow orifice, you will not get the same amount of light as when you have a large space immediately below the point of combustion. The angles at which the burners are bored must be great factors in realizing the largest amount of light. The great thing is to have a proper orifice. If it is too small, the oxygen that passes through is given off as soot—lodging on the ceiling, and causing consumers to cry out about "bad gas," whereas it is the best gas being destroyed that causes this blackening effect. We cannot be too particular in regard to burners; and every gas manager ought to try to enlighten the public as to the best way of using gas. Many people earn a livelihood by hawking burners, which they sell at 4d. and 6d. each, and which they can buy at 4s. 6d. a gross. I am glad to notice that, in some places, Magistrates are punishing these people, who are victimizing the gas consumers. I trust that before long every gas manager will consider it to be his duty to instruct people; and I think that it would be a good thing if gas companies and corporations supplied burners free to all their consumers.

Mr. J. M'CRAE (Dundee): I did not hear the whole of Mr. Hislop's paper; but, judging from the criticism that has followed, I gather that the communication has been of a most unique character. We can therefore scarcely be expected, at a moment's notice, to freely criticize the figures, which have cost so much thought and research. I would endorse, with great earnestness the desirability of educating the gas consumer to use his gas, and not to abuse it.

One serious difficulty which presents itself is this—that if a gas manager suggests a certain burner, or an alteration of the existing gas-burning arrangements, it is always attributed to a desire on his part to increase the consumption of gas. I am sure I express the sentiments of every manager when I say there is no one more satisfied at seeing gas properly consumed than the manager. This, however, can only be accomplished by using the best and most improved appliances. In passing along the streets of the various towns, we have evidence of the way in which gas is destroyed; and it makes a gas manager shiver to see the result of his handiwork thrown away, and to feel that in place of a good light there are large gas bills and general dissatisfaction all round. I hope to see the day when gas-burners will be handed to the consumers free; and not only this, but gas-burners suited to the various elevations of the towns in which they are to be used, because a burner that will do for a consumer on a level with the gas-works will be most unsuitable if used hundreds of feet above that level. I cannot say we have done this in Dundee; but I hope some day to make a move in this direction. Every town should be divided into zones, and for each zone there should be used a certain size and description of burner for ordinary consumers. Of course, for extraordinary consumers, extraordinary arrangements will have to be made. Now that Mr. Hislop has introduced this method, I hope it will be supported by the makers of burners. Any labour spent in this direction will not be lost; for it must result in satisfaction both to the seller and the buyer of gas.

Mr. HISLOP: I am greatly obliged to the members for their favourable criticism of my paper; and am specially pleased at the general expression of opinion that proper burners should be supplied to consumers. I have given much attention to this subject for a long time. I am glad to hear that opinion is ripening on this question; and I hope the new plan will be generally adopted. First of all, I have to thank Mr. Foulis. I am gratified to know that he thinks there are some good points in the paper; and this may encourage further investigation by other members. I hope this will be the result. The matter has long been in my mind, though I have not had time to go into it; and I felt sure there was more in it than has hitherto been considered of any value. I have many times observed that the flame of a burner of a certain condition would go up with the vibration even of a passing vehicle; and the result was to nearly double the amount of light given. This was the first thing which led me to think over the subject, and to make out that there was something in the angle of the holes drilled in the burner. As to the burners being of cast iron, I have to explain that it is not very easy to make them with clay tips. When I learned that the Sub-Committee of the Association were engaged in a similar investigation as myself about three years ago, I gave it up, because we were both troubling Mr. Bray at the same time. However, I procured this extensive series of Nos. 4, 5, 6, and 7 sizes, in order that I might test the whole of the burners with the same gas at the same time; and this I did. Mr. Key made reference to the size of the barrel of the burner. I took care to avoid all forms of burners which might be considered as exclusive in the case of testing gas under Act of Parliament; and I took the plain burner. I did not attempt to test the gas at various pressures, as I found I could not do so without causing it to flare. About 5 cubic feet per hour was as much as I could get at 5-10ths pressure without flaring. Before we can go higher, we must have some controlling medium in the barrel of the burner; but I was careful to avoid anything that might be considered objectionable in the standard test-burner. I might have gone very much further with this matter, and said what was the best angle at which to consume the different qualities of gas at 3, 4, or 6 cubic feet per hour; but I contented myself with keeping strictly to my subject. Of course, I shall be glad if I have opened up a field for further investigation by any of the members; and I have not the slightest doubt that they will come to the same conclusion as I did—viz., that the angle of impingement of the jets has a great deal to do with the amount of luminosity afforded.

The PRESIDENT, in closing the discussion, said it only remained for him to ask the members to accord Mr. Hislop a hearty vote of thanks for his interesting paper, the elaborate tests in which must have cost him a great deal of trouble.

The proposition was carried by acclamation.

MR. COWIE'S PAPER.

Mr. R. Cowie (Tillicoultry) next read a paper entitled "A Year's Experience in the Manufacture of Sulphate of Ammonia." This was given in the JOURNAL for the 7th inst. (p. 245).

Discussion.

Mr. S. STEWART (Greenock): I have listened with pleasure to Mr. Cowie's paper; and, considering the size of his works, I have to congratulate him on his successful working. In large establishments we may get a few pounds more sulphate per ton of coal than he does; but I consider 23 lbs. very good. The clear manner in which he has described his plant, and the success of his operations, should encourage other managers to follow this method. We are very much indebted to Mr. Cowie for his paper.

Mr. G. R. HISLOP (Paisley): We are also indebted to Mr. Cowie for the example he has set to managers all over the country. How often do we find great hesitancy on the part of managers to adopt new processes, although these would certainly result in greater economy. In this respect, we have to compliment Mr. Cowie on the fortitude and courage he has shown in venturing on the experiments described, and on the results he has achieved with his apparatus.

Mr. A. BELL (Clippens Oil-Works): I think Mr. Cowie's failure with his first saturator was not due so much to the impurity in the lead as to the way in which the lead was cast. I had one of these cast saturators; and I found that the lead was being eaten away by the acid. After a careful examination, I discovered that in casting the lead the temperature had been raised too high, and it became oxidized on the surface, and then was mixed in the casting. It was on the oxidized spots that the acid immediately acted. I had the oxidized portions cut out; and the saturator has worked successfully for the past three years. The ordinary lead-lined saturator is more difficult to keep up, on account of the wear and tear. I consider Mr. Cowie's plan of making his sulphate with ordinary commercial sulphuric acid to be an expensive way. If he would use pyrites acid, and allow the sulphide of arsenic to settle out in a separate vessel, he would find that his sulphate would be of a good colour, and be produced more economically.

Mr. DONALDSON (Lochwinnoch): Is it any profit to manufacture sulphate, compared with the price obtained by selling the liquor? I wish to ask the specific gravity of the acid. Mr. Cowie speaks of using 9 tons of acid for 9 tons of sulphate, which I think is a very large proportion.

Mr. P. WATSON (Stirling): Mr. Cowie recently made a remark to me about the properties of sulphate of ammonia as compared with nitrate of soda; and I should like if he would narrate the incident to the meeting.

Mr. J. M'CRAE (Dundee): I have had considerable experience, under different conditions, in the manufacture of sulphate of ammonia. I am pleased to see the manager of a small gas-works giving his experience upon any subject; and his example should be encouraged in our Association, because it has long been felt as a drawback that only the managers of large works come forward with papers. In my experience, gas making is as important in small as in large works; the difference is only one of degree. I would say to Mr. Cowie that he is working on the right lines, and that he has obtained equally good results to those produced in larger works, where more improved appliances are used. Although he is going on in the right direction, he must not stop where he is. I think that by using pyrites acid, he could, by means of a settler, allow the sulphide of arsenic to fall to the bottom, and so the impurity which is so much objected to in pyrites acid will be easily got rid of. To use pure sulphuric acid is a decidedly extravagant plan; and this Mr. Cowie will discover in the course of his experiments. It is prescribed in the Alkali-Works Regulation (Scotland) Act that no pipe shall be connected with the waste gases produced from the manufacture of sulphate of ammonia; therefore it is necessary that the purifiers should be of such an area as to absorb all the foul gases from the production of the sulphate, and must not be connected to any chimney, but be left open. I do not agree with the remark that the consumption of acid is proportionately high, because you require 1.1 tons of sulphuric acid to 1 ton of sulphate of ammonia—just about the proportion used by Mr. Cowie. I manufacture about 400 tons of sulphate in the year, and that is my experience. Mr. Cowie is to be congratulated on coming forward and giving the results of his experience; and I hope other members will follow his example, and be incited to make similar experiments, and report to the Association the result of their investigations.

Mr. J. ROSIE (Wick): Have you, in your experience, ever had a case of a pipe leading to the saturator becoming clogged up, and necessitating a safety-valve? I know a place where a still exploded; and the only cause which could be assigned was the pipe in the saturator choking, and thereby causing increased pressure. I observe that a good many managers work without a safety-valve; and I wish to know whether, in their opinion, this is a safe practice. Managers in small works are apt to forget the corrosive action of ammonia on brass cocks.

Mr. T. D. HALL (Montrose): It seems to me that £60 is a good sum for Mr. Cowie to realize from his liquor alone, carbonizing only 800 tons of coal. I should like him to tell us what he does with his tar; and if he sells it, what he gets for it. If he produces 8 tons of sulphate from 800 tons of coal, it seems to me that that is very good.

Mr. S. STEWART (Greenock): Reference has been made to a safety-valve. I consider that any kind of safety-valve on a still is not a proper thing. What we have at Greenock is a continuation of the filling tube to within an inch or two of the bottom of the boiler; and the liquor, as pumped into the boiler, keeps the pipe clear. There is no evaporation from this sealed pipe; it is only 3 inches diameter. This does away with all risk arising from the choking up of the pipe between the still and the cracker-box.

Mr. COWIE: A gentleman asked what we were doing with our tar. We sell the tar; and I may first say, in answer to his question, that two years ago, when the Company decided to go on with this sulphate business, the whole of our residuals for the year fetched only 5½d. to 6d. per ton of coal carbonized. This year we have received something like 2s. 1d. per ton of coal. This shows the difference. With reference to a remark made by Mr. M'Crae, I may explain that unless the attendant allows the fire to get too strong, causing the gas to be thrown off too rapidly, there is no necessity to have a pipe to the purifier. I intend to increase the area of the purifier, and also to raise the condensing power and add to the number of pipes passing through cold water. We obtained from 836 tons of coal exactly 8 tons 17 cwt. of sulphate. We have no safety-valve on the pipe leading to the saturator; but we have one to the boiler. We do not experience any difficulty with the choking of the pipe to the saturator. I was speaking lately

with an acquaintance of mine in Tillicoultry, who had been visiting the gas-works, and I explained to him that we obtained upwards of 8 tons of sulphate in the year. He told me of a gentleman who bought a good deal of hay from a farmer who gave his grass land rather a heavy dose of nitrate of soda. When a quantity of hay was carried home, the gentleman's horse refused to eat it; and he brought two men to examine the animal's mouth, believing that there must be something wrong with it. Both men declared that there was nothing wrong; and they said the defect must be in the hay. One of them obtained a sample of the hay; and, after examining it, stated that the farmer had dosed his land with too much nitrate of soda. Perhaps this hint may be taken by farmers, so that they may use more sulphate and less nitrate.

A vote of thanks was accorded to Mr. Cowie for his paper.

MR. M'CRAE'S PAPER.

Mr. J. M'Crae (Dundee) read the next paper, on "Coal Tar as Fuel for Steam-Boilers," which appeared in the JOURNAL for the 7th inst. (p. 245).

Discussion.

Mr. R. M. SUTHERLAND (Falkirk): I am not prepared to say very much on this subject; but I have been greatly interested by Mr. M'Crae's paper. The question is one of some consequence to gas managers. At the time when residual products were so low in price, the burning of tar was a question which occupied much attention. Some advocated the burning of tar, and others thought it was a pity to destroy it, seeing that it contained so many fine products. My idea is that it is very much a matter of sentiment. If there was too large a supply of tar, it did not do any harm to burn a portion of it, provided sufficient was left for the market. In London a considerable quantity was burned in one of the large gas-works; and I have no doubt that this had a good effect on the market, and that gas companies generally benefited from it. In regard to the fuel value of tar, I am not prepared to say anything very definite. A few years ago I had some experience in the burning of pitch oil when that article was difficult of sale. Our tanks were full to overflowing; and as we had to do something with it, we turned our attention to burning it. We did so very successfully, and obtained any heat required, which was under perfect control. The experiments were made at a time of the year when we were very busy; and I could not keep such correct data as to warrant me in stating its fuel value. It proved to us that when coal was scarce or dear, we could burn this tar or oil, and get whatever heat was necessary. Mr. M'Crae referred to the use of liquid fuel in a more concentrated form, especially in connection with steamers. I believe that will be done more extensively in the future, more especially if the seemingly inexhaustible supply of petroleum in Russia continues, because there they have the material in a portable and convenient form, and in any quantity, at an almost nominal price. If they manage, by the completion of some of the pipe-lines they are intending to make, to deliver this oil at a seaport at a low price, it will be used as fuel very extensively. I beg to thank Mr. M'Crae for the able manner in which he has brought this subject before the Association.

Mr. G. R. HISLOP (Paisley): I do not rise to give any personal experience on the burning of tar; but it is due to Mr. M'Crae to say that some time ago I visited Dundee, and made a careful inspection of his arrangement for burning tar, and could not help expressing great satisfaction with the admirable apparatus, and the effective way in which the tar was consumed, as well as the results obtained by its combustion. Mr. M'Crae is quite correct in pointing out that what can be profitably done in Dundee may not be the same in other places, and that it will be for other managers to judge for themselves whether it would be economical to burn tar or not. As a rule, the heavy tar is always a drug on our hands; and in most cases it would be economical to burn it. In England our friends connected with The Gas Institute have advocated the desirability of burning a larger proportion of tar, in order to bring up the price of what remains to be sold. That is a matter of opinion. We are greatly obliged to Mr. M'Crae for explaining how we can get out of the difficulty, if we find the pure tar to be a drug on our hands in the ordinary outlets. I give my hearty approval of the system Mr. M'Crae has introduced in Dundee.

Mr. A. MACPHERSON (Kirkcaldy): Like the previous speaker, I cannot give any practical experience; but I have had the pleasure of seeing Mr. M'Crae's system in operation at the Dundee Gas-Works. The perfection to which Mr. M'Crae has brought his plan reflects the greatest credit on him; showing as it does that, with his usual ability, he is ready to seize on anything which, from the situation of the town, will prove of benefit and profit to the Gas Commissioners. I have no doubt that by burning his tar, which he has difficulty in disposing of profitably, he will be enabled to effect a considerable saving. Perhaps he has not had the system long enough in operation to say whether tar has a more destructive effect on the boilers than ordinary firing; and I shall be glad to hear any information on this point.

Mr. W. KEY (Tradeston): I wish that Mr. M'Crae had given a section showing the portion underneath the fire, in order to afford us some idea as to the quantity of air which accompanies the steam and tar into the furnace, and also whether he has any material resting on the bars through which heated air may pass up and strike the spray as it goes into the flue to help the combustion. A great deal depends on that. In one of the Glasgow works, where 300 tons of coal are consumed for steam, the engineer injects steam over the top of the fuel in the furnace; and he states that in this

way he is able to obtain highly augmented steam power. I thought that if he sent the steam in underneath, he would reap more benefit. Perhaps Mr. McCrae can show how the tar and steam are consumed. His arrangements I think are exceedingly simple, and must commend themselves to everyone.

Mr. McCRAE: The effect on the boiler plates of burning tar is a very proper question; and it was a neglect on my part not to mention it. We have been using the tar about a year; and the plates are unaffected. I had expected that the paper was sufficiently detailed in regard to Mr. Key's question; for I say: "In changing from the coal or coke fuel to the tar, little or no difficulty is experienced; and very rarely is a shovelful of any kind of solid material required. The furnace-bars have only to be kept covered to prevent the waste of tar and the too rapid ingress of air." That is really the state of matters. You shut down your coke fire, and turn on the tar without any alteration or rearrangement of the furnace. A little adaptation is required for the regulation of every furnace; but this does not apply to tar especially; our coke always fetches a good price. Of course, if it was of inferior quality, it would not bring so good a price. I have to thank the members for their tender criticism; it is a repetition of the kindness I have so often experienced at your hands.

Mr. STEWART: How many gallons of tar do you use to the ton of coal?

Mr. McCRAE: Against 10 tons 16 cwt. of coal, I use 9 tons 3 cwt. of tar, or 1460 gallons.

A vote of thanks was accorded to Mr. McCrae for his paper; and the meeting adjourned for luncheon.

[The report of the subsequent proceedings will be given in next week's JOURNAL.]

NORTH OF IRELAND ASSOCIATION OF GAS MANAGERS.

ANNUAL MEETING AT LISBURN.

The First Annual Meeting of the members of this Association was held in the School-Room, Railway Street, Lisburn, last Tuesday—Mr. E. STEARS (Lisburn), President of the Association, in the chair. There was a fair attendance of members.

The HONORARY SECRETARY (Mr. J. Whimster, of Armagh) read the report of the Committee for the past year and the statement of accounts. The report was as follows:—

REPORT OF THE COMMITTEE.

Your Committee, in presenting at the first regular business meeting of the Association, a report of their proceedings during the year, feel that they can congratulate the members on the vitality of this, the youngest of the Associations in connection with our industry.

Immediately after the preliminary meeting held in Armagh last year, when it was decided to form the Association, we had applications from four gentlemen to be admitted to membership with us—two as ordinary, and two as extra-ordinary members—whom we received and enrolled accordingly.

The Committee, however, regret exceedingly that in this, the first report, they are called upon to record the fact that Death has made an inroad upon us, and has removed one of our first members—the late Mr. David Orr, Manager of the Monaghan Gas-Works. We have also lost two of our first members, through their removal from the country. But the Committee are sanguine that, through their success in arranging such a satisfactory and attractive programme for the present meeting—a programme which has been posted, so far as possible, to all the gas managers in Ireland—there should be more recruits than fill up the vacancies thus caused.

The Committee desire to bring before the managers of small gas-works the advantage to themselves of co-operating in this work, as it will afford them opportunities of coming in contact, and exchanging experiences with their fellow-labourers, which hitherto they have not had, except at the expense of a journey across the Channel; and they would also wish to impress upon the few managers of large undertakings in Ireland the desirability of identifying themselves with the movement, so as to give it impetus, and encourage their weaker brethren in the work of mutual improvement.

It was remitted to your Committee to frame a set of rules for the government of the Association. This, was done; the rules being drawn on the basis of those of the North British Association of Gas Managers. They were printed, bound up with the report of the preliminary meeting, and a copy sent to each member. The Committee trust that this part of their work will meet with the approval of the general body of the members.

As will be seen from the financial statement, also presented, the balance is on the right side of the account; and though the sum in hand (18s. 8d.) may be small, the Committee have satisfaction in that the Association is able to begin its second year so well.

Signed on behalf of the Committee

EDWARD STEARS, *President.*

JAMES WHIMSTER, *Secretary.*

Lisburn, Aug. 14, 1888.

Mr. W. S. STORMONTH (Coleraine) formally proposed the adoption of the report and statement of accounts.

Mr. A. WADDELL (Newtownards) seconded the motion.

The PRESIDENT put the resolution to the meeting, and it was carried unanimously.

NEW MEMBERS.

The next business was the admission of new members. Three gentlemen were admitted—Mr. J. Gibb (Newry) as an ordinary member, and Messrs. Walter King (London) and Johnstone (Edinburgh) as extra-ordinary members—on the motion of Mr. R. Ross (Dungannon), seconded by Mr. R. MERRILEES (Castleblayney).

ELECTION OF OFFICE-BEARERS.

The next business was the election of Office-bearers and Committee for the ensuing year.

The SECRETARY remarked that the Committee had given this matter a great deal of careful attention, and had experienced some difficulty in proposing the names of gentlemen as office-bearers,

having regard to the fact that the membership of the Association was at present so small. However, the Committee had decided to name as President for the ensuing year Mr. Featherstone, of Dundalk; and in accordance with that decision, he (the Secretary) had great pleasure in proposing that Mr. Featherstone be elected President.

Mr. R. ROSS (Dungannon) seconded the motion.

No other candidate being proposed,

The PRESIDENT declared Mr. Featherstone unanimously elected.

The SECRETARY said he begged, on behalf of the Committee, to submit the names of the following gentlemen as members of the Committee for the ensuing year:—Messrs. R. Ross (Dungannon), J. Nisbett (Portadown), J. Mearns (Banbridge), A. Waddell (Newtownards), T. Frizelle (Holywood), and A. Gibb (Newry).

The PRESIDENT said those were the names suggested by the Committee; but it was open to the members to elect other gentlemen if they thought fit.

Mr. J. ROBB (Limavady) said he had great pleasure in proposing that the names recommended by the Committee be adopted, and that these gentlemen be the Committee for next year.

Mr. R. MERRILEES (Castleblayney) seconded the motion, which was carried unanimously.

The SECRETARY said the only remaining question was that of the election of a Vice-President. On this matter the Committee had not come to any decision, and were not prepared to make any recommendation. They thought that perhaps the Association could manage to do without a Vice-President until they got into working order. Then there was the question of a Secretary and Treasurer, and also of an Auditor. For the last-mentioned position the Committee suggested Mr. J. Todhunter (Ballymena).

Mr. A. WADDELL (Newtownards) proposed that Mr. Todhunter be elected as Auditor.

Mr. W. NISBETT (Aughnacloy) seconded the motion, which was unanimously carried.

Mr. R. ROSS (Dungannon) said the only office remaining to be filled up was that of Secretary and Treasurer; and it gave him great pleasure to propose that Mr. J. Whimster, who had rendered such valuable assistance in establishing the Association, and who had from the beginning discharged the onerous duties of Secretary and Treasurer in a manner that entitled him to their warmest thanks, be re-elected to the position for the ensuing year.

Mr. W. R. FEATHERSTONE (Dundalk) was pleased to be permitted to second the resolution. He thought they could not have a better gentleman for their Secretary than Mr. Whimster. He was always willing to look after the interests of the Association; and, in addition to that, he possessed the ability to do so.

The PRESIDENT, in putting the resolution, said he was sure every member would agree with him that in Mr. Whimster as their Secretary and Treasurer they had "the right man in the right place."

The resolution was unanimously adopted.

PLACE OF NEXT MEETING.

The SECRETARY then proposed that the next meeting of the Association be held at Dundalk, as a compliment to their new President.

Mr. R. ROSS seconded the proposition.

Mr. J. ROBB thought the meeting should be held at some place which would be more convenient for the southern and western members. He suggested they ought to meet them half way.

The PRESIDENT said that at some future time perhaps they would be able to consider Mr. Robb's suggestion; but at present he did not think they could see their way to do so.

The resolution was then passed unanimously.

Mr. R. MERRILEES suggested that the next meeting should be arranged for the last week in May, any time in June, or the first week in July.

The SECRETARY said he did not think the first week in July would be practicable. It would certainly not suit him; and he thought it would be very inconvenient for the majority of the members.

After some further remarks,

The PRESIDENT said the meeting did not seem to be of the same opinion as Mr. Merrilees; and for the present it would be better to allow the date of next meeting to remain unchanged.

The subject then dropped.

The PRESIDENT next proceeded to deliver the following

INAUGURAL ADDRESS.

Gentlemen,—In commencing this brief address, I must thank you for having chosen Lisburn as the first place of meeting of our newly-formed Association, although I am afraid I cannot show you here anything novel in the operations connected with the manufacture of gas. I find, as a rule, that directors do not like to try new schemes which are likely to cause any additional expenditure; but they prefer to continue working on the old lines. Perhaps, if their dividends were to fall below 10 per cent., they would be more speculative.

In the North of Ireland, gas companies have (like many others) found it necessary to their welfare, in face of the competition of electric light and petroleum, to reduce the price of gas. The best means of maintaining the value of our property is by keeping the price of the commodity we supply as low as will pay a fair dividend, as there is no question that the competition of petroleum and electricity with gas is very sharp. As far as Lisburn is concerned, we find that very few new customers are obtained from small private houses with a rental up to (say) £20 a year. They nearly all consume oil, although the price of gas is only 3s. 9d. per 1000

cubic feet. One thing which operates against my Company procuring the custom of the poorer class of residents, is that we require a deposit of 10s. as security. This no doubt reduces the amount of bad debts; but it is detrimental to an extension of our business. In regard to the electric light, we have one mill in our district partly illuminated by this means; and I must say that it seems to give satisfaction. The owners of another mill are also seriously contemplating its adoption in an extension of their premises; and the promoters of the light say that the cost will be much less than gas. There is no doubt that there is more danger of our mill customers going over to electricity than the general public, as they can supply motive power and supervision at low cost.

I intend making a few general remarks on gas manufacture from my own point of view, and hope that these will meet with approval. I may here incidentally remark, as some of our members may not be able to be present to-day, that we manufacture 26 million cubic feet of gas per annum; the maximum make being 160,000 cubic feet per 24 hours. As nearly half our make of gas is sold to mills, the heaviest output is in the winter months. Dealing first with the retort-house, our retort-benches consist of sixes, set on Cathels's system. The only alteration I have made is in the furnace. I use cast-iron bars 2 ft. 6 in. long, the furnace 12 inches wide, and double doors; thus giving a deep fire, and generally allowing some air to pass in through a sight-hole left partly open over the furnace. I take the opportunity here of suggesting to those members who may have had some experience with regenerative furnaces, that we shall be glad if they will give us some information on this important subject.

In regard to the question of tar burning, I have tried this both with and without steam, and must say that I prefer the latter plan, as it does not give such intense heat in the furnace, and also causes less trouble and noise in working. The tar-supply tank is fixed outside the retort-house, and is filled with tar from the well by an injector, at the same time permitting the tar from the pipe leading from the hydraulic main to flow into it—the overflow going back again to the same main lower down. I found some difficulty at first in getting this plan to work. This, however, I overcame by introducing a gas-burner in the wooden box where the tank is situated; and by keeping the temperature up to 70° Fahr. I have not had any trouble on this point, and do not find it necessary to use screens to keep out the dirt. My experience leads me to the conclusion that 2 gallons of tar are about equal to a bushel of coke. I may mention that the tar was used in the ordinary furnace. The fire was allowed to clinker up, and only a sufficient opening left to consume the tar and its products with a few bushels of coke daily. We clinkered the fire out perhaps once or twice a week. When burning tar, the upper furnace-door is substituted by one having four 1-inch holes drilled through it for the air supply.

As to the exhausters, we have three—one being a Laidlaw or rotary exhauster, and the others a Beale and a steam-jet. The latter is made of 1½-inch pipe, which is sometimes used for six retorts in the summer. For general use, I prefer Laidlaw's exhauster, as it costs less for lubrication and attention, although the amount of "slip" in it is very large. It answers well for all but the heavy work, when there is a strong back pressure, and then Beale's is more suitable. For Beale's exhauster we use creosote oil, which answers the purpose well, and is cheap. After leaving the exhauster, the gas passes through an ordinary scrubber, worked with ammoniacal liquor; and we are now fixing also one of Kirkham, Hulett, and Chandler's "Standard" washers to work with water. The gas is then purified with lime in the ordinary way.

It may be in your recollection that we had an explosion during last winter. It took place at 4 o'clock in the morning, just as the men had finished the 3 o'clock charge. It was caused by a seal-cup at the bottom of the centre-valve blowing; the lime in the purifiers being too dry, which caused more back-pressure than the seal-cup would stand. The flooring of the purifying-house being boarded over, the hollow space below became filled with gas; and it eventually caught fire from a lamp in the yard. Four men were taking water to fill a syphon which it was thought was unsealed, when the explosion took place blowing the men away and unslating the purifier-house, besides doing other damage to the works. Fortunately, the only injury to the apparatus was a crack across the bottom of one of the purifiers. The men were taken to the infirmary, where they were under care between two and three months; the Company paying them full wages during the whole time.

I have this summer fixed a hydraulic safety-valve to the inlet of the scrubber, consisting of a covered tank 3 feet deep by 14 in. by 12 in., with a division 2 inches from one side going down to within 3 inches of the bottom. The working pressure is regulated by a ¾-inch pipe for overflow at the water-line; the inside of it being carried 6 inches downwards, so as not to be affected by the ebullitions of the water when in action. There are also two rows of tiles laid partly across the inside of the chamber, 6 inches and 9 inches above the water-line, to check the ascent of the water, as it is thrown upwards by the gas. A 4-inch pipe conveys the gas to the top of the scrubber; so that in case it operates, the gas will be blown into the atmosphere out of danger. The gas-inlet is in the 2-inch chamber; and the outlet-chamber being larger, will prevent so much water being blown out of it through the overflow when put in action. I made 4-inch connections to this valve, which I considered large enough to take off the make of gas in case the inlet to the gasholders should be closed by accident; and

thus preventing the purifier lutes blowing, and not allowing too much gas to flow back from the gasholders in case the holder inlet-valve was open.

We have manufactured sulphate of ammonia at our works for about twelve years. I believe I may claim to be the first in this district to do so. The apparatus employed I may describe as "home made;" the capital outlay being under £100. All the tanks, including the saturating-tank, are lined with sheet lead 6 lbs. to the foot. The saturating-tank is lined with lead in one piece, what the plumbers call pig lugged—i.e., the ends are turned up. The joints of the other tanks are joined with coarse solder. The liquor is pumped into a tank supplying the boiler by the same pump that supplies the scrubber. The boiler is fired with breeze. There are then a saturating-tank, two settling-tanks, and two evaporating-tanks. The liquor is heated by the waste steam from the engine after it has passed through a water-heater for the boiler feed. The man who sells coke makes the sulphate of ammonia, with the aid of an assistant, in the winter months. When I commenced the manufacture, the salts were made in the saturating-box; but it was found more convenient to make it by working the saturating-box with half water and half acid at starting, and then removing the neutralized liquor to the settling-tank, and from thence letting it down to the evaporating tank below. This plan enables the man in charge to leave the boiler filled with ammoniacal liquor at night, having made up the saturating tank with sufficient acid and water to neutralize the steam from the boiler; so that all the night stokers have to do is to keep up the fire, and shut the damper and lift the safety-valve when the water gets to a certain level in the gauge. We generally make about a ton of salts to every 110 tons of coal carbonized. I have given these details, as there may be some manager who may be under the impression that it requires a large outlay to set up sulphate works, I may say there are no brick buildings connected with the apparatus, and the tanks are under wooden sheds.

With regard to the question of wet and dry meters, I may say that I am an advocate of the latter—in fact, for the last five years we have not bought any wet meters. The consumers always prefer the dry meters, as they give less trouble. As to our street lamps, they are all provided with governors. I should strongly advise those managers who have not adopted governors to do so; and I can assure them that the results will be not only a much more satisfactory light, but a saving of gas.

I have upon several occasions met with managers of small works who, upon my inquiring what pressure they supplied at during the night, could not tell me, as there was no pressure-gauge on the works. The general plan seems to be to put the gas on full at night. Those who have (say) a 4-inch valve which they open and shut, should have a 1-inch or ¾-inch governor acting as a bye-pass round the valve; and so work the night pressure after eleven o'clock and the day pressure with it. By having a pressure-gauge on the outlet, the pressure can be reduced from (say) 5-10ths inch in the daytime to 1 inch after 11 p.m., instead of allowing the gasholder pressure to remain on the town all night.

The question of Sunday labour in gas-works has recently received much attention. In our case we give the day stokers a half holiday—that is, half the men come to work at six o'clock, and go off after the twelve o'clock charge is finished; the other half remaining during the afternoon. The men receive full day's wages. The work is generally eased on Sundays by laying off a bed or two according to the state of the gasholders.

In conclusion, I may observe that in my opinion it is not unlikely in the future we may find large works adopting a system of manufacturing water gas on the plan advocated by Mr. A. Wilson of Stafford, which resembles a cupola used by ironfounders for melting iron, and that a method will be found of injecting gas tar into it, so that a gas of low illuminating power may be used for mixing with ordinary gas, and used for day supply (say) for eight months in the year. There are some gas companies who have a large demand for gas for cooking purposes, &c., and who perhaps are only compelled by their Act to supply 14-candle gas, whereas they generally give from 16 to 17 candle gas. The only difficulty I can foresee, is that at lighting time the consumers on the distant parts of the mains might complain of the low illuminating power of the gas during the early portion of the evening. There is, however, no doubt that a scheme of this nature would require more attention than the ordinary plan of coal gas making, and certainly would not be suitable for small works.

Mr. FEATHERSTONE said he had great pleasure in proposing that the best thanks of the Association be given to the President for his very admirable address. He (Mr. Featherstone) had listened with the greatest appreciation to the address, which was full of valuable information which he was sure would prove of great advantage to every member of the Association. They would have an opportunity later on of reading it; and he was sure they would obtain very useful hints from a perusal of it.

Mr. FRIZELLE seconded the motion, which was carried unanimously.

PAPERS AND DISCUSSIONS.

The SECRETARY said he was sorry to have to announce that Mr. T. Travers (Cork), who had promised to read a paper, entitled "How can we best Assist our Consumers?" had written to say that he would not be able to be present, as he had to attend the half-yearly meeting of his Company. Further than this, Mr. Travers had not sent his paper; and therefore the meeting would not have an opportunity of listening to what he (the Secretary)

was sure would have been an able and interesting communication. However, they had three other gentlemen present who had prepared papers on subjects of importance.

The other papers on the *agenda* were then read, as follows:—“The Utilization of Tar at Dundalk,” by Mr. W. R. Featherstone, of Dundalk; “Experience with Mr. G. R. Hislop’s Regenerative Furnace,” by Mr. A. Waddell, of Newtownards; and “Retort-Setting for Small Gas-Works,” by Mr. J. Robb, of Limavady. These, with the necessary illustrations and the discussions, will be given next week.

VOTES OF THANKS.

Mr. WADDELL proposed that the cordial and hearty thanks of the meeting be given to the President, for the ability with which he had presided over the proceedings.

Mr. GIBB said it gave him great pleasure to second the proposition; and in doing so he desired to add, on behalf of the members generally, that Mr. Stears’s conduct during his year of office, and his anxiety on all occasions to serve and forward the interests of the Association, which, under his presidency, had prospered very much, had earned for him their warm and cordial thanks.

The resolution was carried with applause.

Mr. GIBB asked to be permitted, in the name of the members of the Association, to thank their Secretary and Treasurer for the way in which he had during the past year discharged the duties of his position. Mr. Whimster had been most indefatigable in looking after the interests of the Association, and he deserved their thanks.

The proposition was cordially agreed to.

The PRESIDENT thanked the proposer and seconder of the vote for the kind expressions they had made use of with regard to himself, and also the meeting for the equally kind manner in which they had received the vote, for which he was very much obliged to them. He hoped—and he was sure—the Association had a prosperous year’s work before them; and he trusted that their next meeting in Dundalk would be even more interesting than the present one had been.

The SECRETARY also desired to avail himself of the opportunity of thanking Mr. Gibb for his kind remarks with regard to himself, and the meeting for their vote of thanks. He could assure them that it was a pleasure to him to be able to do anything in his power for the success of the Association and the furtherance of the work in which they were all engaged. He thought that their work was a good one; and he hoped it would be successful in bringing them and their brethren more closely together, to their profit and advantage. He urged the members to cordially combine to forward the interests of the Association, which he was sure would go on and prosper.

The proceedings then terminated.

The members subsequently dined together at the Railway Hotel, under the presidency of Mr. Stears.

GAS LIGHTING BY HIGH-POWER BURNERS.

In the course of a communication presented to the Société Industrielle du Nord de la France by the Manager of the Wazemmes Gas Company, he made the following remarks on gas lighting with high-power burners:—

For gas of a standard illuminating value, the lighting power increases with the temperature of the flame. It also increases, under favourable conditions, if the quantity of gas consumed by the burner in a certain period is augmented. Thus, two burners consuming 60 litres (rather more than 2 cubic feet) of gas, placed in juxtaposition, produce less light than one burner consuming 120 litres. As it is impossible to indefinitely increase the supply to ordinary burners, multiple-flame burners have been invented, in which two or more ordinary flames are united so that they may impinge upon each other. By an ingenious arrangement for bringing the air into contact with the multiple flames, two excellent types of lamps are obtained, consuming respectively 700 and 1400 litres per hour, which meet with a rapid demand in Paris, and in many other towns, for lighting wide public thoroughfares, squares, and large open spaces. If, however, it is desired to obtain a flame with a much higher temperature, it is necessary to resort to a special arrangement for heating the air intended for combustion with the gas. The principle of heating the air by means of the waste heat escaping with the products of the waste gas—the regenerative principle—was adopted by Mr. F. Siemens, and applied not only to gas-burners, but to high-temperature stoves. With the Siemens burner on the regenerative principle the following results are obtained:—With a consumption of 150 litres per hour, the light of from 1 to 3 Carcels; 250 to 300 litres, 6 to 7 Carcels; 600 litres, 15 Carcels; 800 litres, 20 to 22 Carcels; 1600 litres, 46 to 48 Carcels; 2200 litres, 72 Carcels. Unfortunately, the construction of the Siemens Argand lamps is very delicate, and, moreover, they have the disadvantage of being heavy, and rather unsightly. In Germany they have been widely adopted; but in France they have met with but little success. The Schülke lamp is made on the same principle; and this appears to be too delicate to come into general use. One of the latest burners of the regenerative class is the Wenham, which has been before the public for some time in England, and is now being adopted in France. In point of fact it is merely a very effective improvement on Breittmayer’s burner, from which it differs only in its construction; being produced in some elegant styles, which lend themselves perfectly to the

decorations of private houses. The No. 2 lamp of this type, with a consumption of 283 litres (10 cubic feet) per hour, has given 126 candles, in a vertical direction without reflectors; horizontally, 50 candles. But the gas employed in the tests had an illuminating power about 20 per cent. higher than that usual in Paris. When experimenting in Paris with a No. 3 lamp in a vertical direction, it showed a consumption of 34.6 litres (1.2 cubic feet) per Carcel obtained. The Wenham lamp is constructed to give light in a vertical direction; and by adopting a large reflector, the illuminating power is increased 18 per cent. in a vertical line, and 55 per cent. at 80°, which is a highly satisfactory result. There are at present five sizes of these lamps. There is also the Delmas hot-air burner, in which the batwing flame is completely enclosed in a glass, mounted with a sheet-iron casing, heated by the products of combustion, through which the air passes on its passage downwards to feed the flame; and it thus increases the temperature, improves the illuminating power, and produces a beautiful steady light. Mention also may be made of the Siemens radiated heat-burner, by means of which the heating of the air is effected simply by the radiation of the metallic parts of the appliance which are in contact with the flame. These burners produce the light of 1 Carcel (9.5 candles) with a gas consumption of 70 litres (about 2½ cubic feet), and are therefore, from an economical point of view, intermediary between the high-power and regenerative burners. This degree of economy can be ascertained by an ingenious arrangement of the air supply in a burner with holes, which has been made in the laboratory of the Wazemmes Gas Company by M. Verl , the Engineer, who has invented a very simple burner called the “Lillois,” with which the light of 1 Carcel is obtained with a consumption of 70 litres. This produces a tulip-shaped flame, and it has a specially constructed glass arrangement on the outside for regulating the combustion. Comparing the above-mentioned burners with each other, we arrive at the following results:—The “Lillois” burner consumes 70 litres of gas per Carcel; the Siemens ordinary, 70 litres; the Siemens-Breittmayer, 35 to 39 litres; the Wenham, about 35 litres. Taking this into account, and considering that a Carcel corresponds with 105 litres of gas consumed in the Bengel form of burner, we see that the economy in gas might, by employing these burners, reach from 33 to 71 per cent. If this is compared with the batwing burner, which produces the light of 1 Carcel with a consumption of 120 litres of gas, the economy is greater—varying, according to the type of lamp, from 41 to 85 per cent.

THE GENOA WATER COMPANY’S CASE.—In the course of a letter recently addressed by Colonel Hughes-Hallett, one of the Directors of the City of Genoa Water-Works Company, Limited, to Mr. Webb Hayward, of Rochester, he states that the Board intend to appeal against the judgment of Mr. Justice Kekewich in the case reported in the JOURNAL last week (p. 293). The word “subscribed,” which was used in the prospectus in reference to the £200,000, and which was alleged to have misled the plaintiffs, was inserted under the advice of Counsel; and when the Directors found that a mistake had been made, they sent out a circular explaining the matter, and offering any debenture-holders the chance of having back the money they had subscribed, if they wished. Colonel Hughes-Hallett says the people who brought the action “not only took no advantage of the offer, but accepted the dividend each year.” The case will, if necessary, be carried to the House of Lords; and the Board appears to be confident of eventual success. At any rate, they ask for a suspension of judgment on the part of the public until the higher tribunals have been consulted.

THE EDINBURGH GAS-WORKS ARBITRATION.—Mr. George Livesey was in Edinburgh on Thursday and Friday last in connection with the arbitration between the Edinburgh and Leith Corporations’ Gas Commissioners and the two Gas Companies, to which reference has already been made in our columns. The two chief points in dispute were: (1) What were the implements which had to be specially paid for under the Purchase Act; and (2) what was the sum to be paid for the stock of coals which the Companies respectively had to hand over. The proceedings occupied the whole of Thursday; and on Friday morning Mr. Livesey made his award. He has decided that “no item or article is to be valued and paid for which was used or required for the efficient working of the respective undertakings at their maximum production of last winter,” and also that “only those stores of materials referred to in section 90 of the Act, and all implements, meters, and pipes in store or in hand—whether new, or unused, or not—which are in excess of the quantities of materials, implements, meters, and pipes which were required at the aforesaid period of maximum working, are to be valued and paid for, as provided in the said Act.” The effect of this decision, says the *Scotsman*, will practically be a reduction of the claims of the Companies by upwards of £5000. In carrying out the decision, the lists of both Companies were gone through, and the various articles disallowed were withdrawn. The Arbitrator and the parties’ representatives thereafter proceeded to the works to value the stores to be paid for. He then proceeded to adjust the various claims agreeably with his award, and visited the works for the purpose of examining the implements and stocks which have to be paid for by the Commissioners, in order to attach a value to the same. He fixed the price of the unused gas in the gasholders and pipes as on the 1st of August at 2s. 6d. per 1000 cubic feet. The valuation of the coal in store or in hand is to be made at the contract price.

Register of Patents

SELF-GENERATING GAS-BURNERS AND APPARATUS CONNECTED THEREWITH.—Norman, J. J., of Southwark Bridge Road, London. No. 9665; July 9, 1887. [8d.]

This invention has for its object improvements in patent No. 1828 of 1884, whereby it was proposed to increase the utility and convenience of the apparatus described therein, and render it more easily applicable to a variety of uses, where the generation and ready control of a great volume of heat and a high degree of temperature, as well as perfect combustion and absence of smoke, are desired—thus rendering it peculiarly suitable for use in inflating balloons for war and other purposes, whereby "greater convenience and economy in aerial navigation are obtained, and at the same time greater facility of, and safety in their employment."

GAS MOTOR ENGINES.—Lindley, H., and Browett, T., of Salford. No. 11,345; Aug. 19, 1887. [11d.]

This invention relates to gas motor engines of the kind wherein a charge of explosive gas or vapour or spray mixed with air is drawn into a cylinder, then compressed, then ignited, and afterwards expelled during four successive strokes of a piston corresponding to two revolutions of the engine; and the object of it is to simplify the construction of such engines, and to enable the power produced to be governed in proportion to the load.

To this end the waste products resulting from the explosion are expelled from the cylinder by providing at or near the end of the cylinder lying towards the crank-shaft of the engine, holes or ports in such a position that they are uncovered by the piston on the completion of its out-stroke—that is, its stroke towards the shaft. These ports, which may be of small diameter so as not to open too early, serve to get rid of any excess of pressure over atmospheric pressure that may remain in the cylinder at the end of a working stroke. After the crank has passed the dead centre, the piston begins to return; and it then expels a small portion of the contents of the cylinder through the holes already mentioned, continuing to expel until it has again covered such holes. If, however, it be deemed advisable to prevent such displacement by a loaded check-valve or other means, the piston during the remainder of its in-stroke deals with the bulk of the products in the cylinder in one of two other ways, premising that, in addition to the holes already mentioned, the engine is fitted with a separate exhaust-valve at the other end of the cylinder (the farther end from the shaft). This valve is capable of being mechanically moved by a lever, cam, or other means, and worked from the engine itself; the actuating mechanism being so arranged as to operate or not under the control of the governor. A valve is also provided whereby the charge of air and inflammable vapour or spray can be admitted into the cylinder. This may advantageously be of the lift type, and self-acting—that is, adapted to lift when there is a partial vacuum or reduction of pressure in the cylinder; or means may be provided to operate it mechanically by a slide such as is frequently used in gas-engines for this purpose.

GAS MOTOR ENGINES.—Embleton, D., of Hunslet, near Leeds. No. 11,717; Aug. 26, 1887. [8d.]

This invention has reference to an improved construction of gas-engine of the type described in patent No. 2447 of 1886, in which there is an explosion at every revolution or alternate stroke, and in which there is admitted to the cylinder through a hole or radial holes (uncovered by the piston as it approaches the termination of its outward stroke) a scavenging charge of air, and afterwards a combustible mixture of gas or vapour and air, and the contents of the cylinder are compressed on the inward stroke, during which also products of combustion and air are expelled through the inner end of the cylinder. In this way, on the conclusion of the inward stroke, there is enclosed within a chamber at the inner end of the cylinder—and which may advantageously be of larger diameter than the working cylinder—a practically homogeneous compressed charge of combustible mixture, which is ignited and expanded so as to propel the piston outward until it uncovers the holes. Air is thus admitted first; and afterwards a further charge of combustible mixture (as before), which is compressed on the return stroke, during which the products of combustion from the explosion, as also air admitted, are expelled; and so on at each revolution or double stroke of the engine. In this engine the chamber into which the combustible mixture is compressed preparatory to ignition is not made long, and of a gradually diminishing diameter; but is made short in proportion to the stroke of the piston, and of uniform diameter, whether such diameter be the same as that of the working cylinder or not. Satisfactory results may be obtained, says the patentee, by the use of an ignition chamber having a cubical capacity of from about one-fifth to one-fourth that of the working cylinder. Means may also be provided to ensure a thorough admixture of air and gas or vapour prior to entering the working cylinder.

LAMP AND GAS COOKING-STOVES.—Bowen, E., of Perry Barr, near Birmingham. No. 12,508; Sept. 15, 1887. [8d.]

This invention is designed to increase the superficial heating surfaces of gas-stoves; so that the maximum amount of heat is obtained for a minimum expenditure of gas. The stove consists of a series of rectangular shaped plates, connected together so as to form an enclosure, with horizontal divisional spaces to constitute heating chambers, which are situated between vortical flues or passages, leading respectively from the burner chamber at the base of the stove, and from the horizontal heating chamber leading to a crown space at the summit of the stove.

LIGHTING REGENERATIVE GAS-LAMPS.—Fournoss, H., of Manchester. No. 12,554; Sept. 16, 1887. [8d.]

This invention relates to means for lighting regenerative gas-lamps—more especially of the now well-known Fourness type; but is applicable for use with any lamp the burner of which is enclosed in a glass shield. The proposal is to ignite and shoot a tongue of flame into the interior of the shield and towards the burner; so that when the gas is turned on, the lamp is immediately lit without disturbing the shield, and without

providing any ports or openings therein for the introduction of tapers or other lighting media.

In the illustration given of a Fourness lamp, the supply of gas to the burner A is controlled by a valve B operated from beneath the lamp; while the supply to the lighting apparatus is taken from the pipe C by a T-piece and a branch E, by which a constant supply of gas is led to the tap F. This tap has two outlets—one at G, and one at H; the latter being directed downward towards the interior of the lamp. When the tap is turned on, gas issues from both outlets. Just opposite to the outlet G an opening is formed in the surrounding shield of the lamp; and immediately opposite to the outlet H another opening is made in the upper part of the lamp. When the lamp is to be lit, the tap is turned and the gas issuing from G is ignited. This flame strikes and ignites the gas issuing from H; and the flame is shot downward into the interior of the glass. The valve B is then turned, and this allows gas to issue from the burner A; and it is immediately ignited by the flame from H, and the lamp is lit. The tap F is then turned off until again required.

PRESSURE INDICATOR FOR FOUL GASES.—Thomas, A., of West Cowes, and Thomas, P., of Buckingham. No. 1366; Jan. 30, 1888. [8d.]

In reference to this invention, the patentees say: We make the indicator of two glass tubes—one inside the other. The outer one has a solid bottom, while the inner one is open at both ends, and is slightly the longest. At the lower end of the back-plate (of wood or metal), we fix a small shelf, which has a hole sunk part of the way in to receive the solid end of the outer tube, or a ferrule may be fixed upon the shelf which answers the same purpose. At the top of the back-plate we fix a ring, through which the outer tube is passed. We make a metal guide to stand in the bottom of the outer tube, and one to clip the top of the tube. Each of these guides has a hole in the centre through which the inner tube is passed, so as to keep the inner tube in the centre of the outer one; or the solid end of the outer tube can be made dome-shaped, and the open end brought into a smaller diameter. This dispenses with the two last-named guides, as the alteration to the outer tube will keep the inner one in the centre. To admit of the water passing freely from the inner to the outer tube, the lower end is bevelled. To use the indicator, the gas is passed (by means of a portable pipe) into the inner tube; and coming in contact with the water, displaces part of it, driving it into the outer one—the difference between the two water-levels showing the amount of pressure upon the apparatus.

IMPROVEMENTS IN STARTING GEAR FOR GAS-ENGINES.—Deboutteville, E. D., and Malandin, L. C. P., of Fontaine-le-Bourg, France. No. 8300; June 6, 1888. [6d.]

This invention relates to improvements in starting gear of the class described in patent No. 2305 of 1888. By means of the present invention, the starting of the engine can be effected without working the piston by hand in order to draw in the gaseous mixture during a fraction of the stroke, and to compress the charge thus drawn in as described in the former patent. With this object, the cylinder is provided with a cock or valve, by means of which the inert gas in the cylinder can be discharged.

GAS-LAMPS.—Thompson, W. P.; communicated from Herzfeld, J., of Berlin. No. 8532; June 11, 1888. [8d.]

The object of the present invention is to prevent the decomposition of the gas in the supply-pipes of regenerative gas-burners, or at least to reduce it to a minimum, and also to provide an arrangement of the pipes which will enable anyone to clean them easily, by simply brushing their inside surface, without having to remove the lamp at all. By this arrangement, the gas which flows through the pipes at a great velocity gets heated to a certain extent, but not enough to cause the separation of the carbon. The gas then enters a special distributing chamber, in which it is further heated, so that the separation and deposition of the carbon take place in the chamber, which is thus not liable to be stopped.

WIND PRESSURES ON GASHOLDERS

[The correspondent whose letter we give herewith has good and sufficient reasons for withholding his name from publication; but, in order that due weight may attach to the position he takes up on this subject, it may be mentioned that "Theory and Practice" is the *nom de plume* assumed by the gentleman who is contributing the interesting series of articles in the JOURNAL (commenced in Vol. L.), under the title of "The Guide-Framing of Gasholders."—Ed. J. G. L.]

SIR,—There seems to be a great deal of mystery in the minds of some people as to the manner in which wind pressure acts upon a gasholder, and the effect it produces. Perhaps the following remarks may help to clear up the misunderstanding, which has evidently taken possession of the writer of the leading article in the JOURNAL for the 31st. ult. He remarks: "Up to last year it was generally accepted that the overturning force of the wind, exerted against a gasholder from one direction, tended to push the holder along a horizontal plane, and could be equally divided among the number of guide-rollers brought into play." Mr. Corbet Woodall and Mr. Foulis are both quoted as holding this view; and Mr. Hunt is looked upon as a waverer. The writer calls this the "fundamental assumption of the old theory," and "the old theory of gasholder stability;" and he states that it is now contradicted by the experiment at Rotherhithe. This is due to a confusion of ideas on the subject—viz., confounding the loading of a beam with the manner in which the beam resists the load.

A gasholder may be looked upon as a beam fixed at one end; or a cantilever, as it is generally called for brevity. It is "uniformly loaded" from top to bottom (wind), as stated by Mr. Woodall. No one can reasonably contend that the wind pressure is not, to all intents and purposes, a uniform load that is distributed equally from top to bottom over the sides of the holder.* This pressure is transmitted to the guide-framing, through the roller carriages, uniformly from top to bottom. The force (or load) is horizontal in direction, as stated, and tends to sheer off the guide-framing at the base in a horizontal plane.

This is all perfectly correct, as far as it goes; but we are asked to believe that these elementary principles in mechanics, which have been proved up to the hilt, are upset by the experiment at Rotherhithe. The most elementary text-book in Applied Mechanics shows that uniform load on a cantilever induces a shearing force at the fixed end equal to the total load, and at right angles to its length. The gasholder which is subject to precisely the same conditions of loading cannot claim exemption from this law or principle in mechanics.

A cantilever, like all other beams, is not only subject to shearing strains due to the load tending to push it along a plane at right angles to its length—i.e., in the same direction as the load acts, and which is horizontal in the case of a gasholder cantilever—but, as is well known by every engineer, it is likewise subject to compression and tension along its fibres, on opposite sides of the neutral axis, due to the bending moment. It is likewise subject to buckling, crippling, and wrinkling strains.

In the old style of gasholders, the bell or floating part of the holder pushed against several cantilevers in the shape of a number of massive columns or standards, lightly tied together by girders, but practically acting like so many independent cantilevers. But in the new style, the bell pushes against one cantilever only—viz., the whole guide-framing in which it is enclosed. Mr. George Livesey, much more than a "year ago," clearly recognized and advocated this latter method of construction—viz., making the whole structure into one complete braced-frame cantilever, instead of the old mode of several cantilevers. There is no "reconstruction of theory" or "new theory" demanded. The theory remains the same; it only becomes a matter for deciding which is the better plan for meeting the demands of theory—to put up one Livesey braced-frame or several independent cantilevers, to resist the horizontal push of the wind. This is a wide question into which space forbids me to enter.

The writer of the article also infers that, because the top lift does not blow over when the top part of the guide-framing is done away with (as at Rotherhithe), it does not push at the top guides when the framing is carried to the full height, as usual; or, in other words, that the top roller-carriages never have any work to do. This clearly shows what false conclusions may be drawn from an "experiment" improperly understood. In the Rotherhithe gasholder, the total horizontal push of the wind is the same as if the guide-framing reached the full height. The resultant horizontal shear at the foot is the same. The bending strain at the foot of the guide-framing is the same. The crippling or buckling strains are increased, because the cups are not so well suited to resist distortion as the strutted top curb is, and therefore render but little assistance to the guide-framing. The great difference in the conditions is this: The bell of the gasholder itself is now called upon to act as a cantilever in its upper lift, which it is not required to do in the ordinary construction. It would undoubtedly push against the top of the guide-framing if there were any to push against; but as there is not, it has to take all the bending strains in itself, caused and created by abolishing the top framing. This is all fully explained, and the nature of the strains pointed out, in the "Communicated Articles" on this subject which appeared in the JOURNAL last, and early in the present year. The push which would in the ordinary way be given out by the top rollers is given out lower down by the dip rollers on the middle lift. The following illustration may make my meaning clearer:—Bed a plank evenly on the ground. It may fairly be said to press the ground equally along its entire length—i.e., the ground is "uniformly loaded." Now remove the supporting earth from under one end—say, for one-third of its length. Are we to infer, because the end of the plank does not break off after the

earth is removed, that it did not exert any pressure against the ground at that end before the earth was removed? We know such an inference to be absurd; and yet that is exactly what we are asked to believe about the gasholder—viz., that because the inner lift does not break off or bend over, it could not have exerted any pressure against the guide-framing if the frame had been carried to the full height.

Another extraordinary statement needs comment. It is this: "If a gasholder will stand in fair weather, it will stand in a storm." This is equivalent to saying that a chain which will not break with a load of 10 tons will, of course, not break with a load of 20 tons—an absurdity.

The writer of the article further states that the best way to solve the problem, and determine the "new theory" is by "direct experiment." On this subject I would only remark that experiments, in order to be understood, must be accompanied by a capacity for drawing correct conclusions, or they are valueless, if not positively dangerous, for experiment (anything which appeals to the outward senses) always carries with it a certain amount of conviction which may be false altogether, of which we now have a case in point. The same experiment may prove opposite things to different individuals. It seems strange that you only have to call anything "practical," and you may have any number of followers; but brand it as "theory," and doubt is at once cast upon it, although experiment unaccompanied by sound "theoretical" knowledge in the subject is very little good. It is useless to resort to experiment for determining the nature of the strains on a gasholder, unless the greatest care is exercised in not drawing hasty and erroneous conclusions.

With regard to making experiments on this question, it is quite unnecessary to work with expensive models. All that need be done is to take (say) an existing three-lift holder, and remove the top rollers, or, for safety, set them back a few inches all round. You then have the inner lift free. Do the same with the rollers on as many lifts as you wish to run up and down independently of the guide-framing; and if the folly of "6 feet of guide-framing only" must be proved "practically," fix rollers on the side of the outer lift 6 feet above the bottom curb, and remove all those working in the guides above that level. Then inflate the holder, and note the result!

In conclusion, I cannot do better than quote Mr. George Livesey's gentle rebuke, when writing on this "6 feet of guide-framing" suggestion (see JOURNAL for April 26, 1887): "It is all very well for a writer to sit at his desk and formulate theories; but to put them in practice would incur a responsibility from which he would probably shrink."

Aug. 10, 1888.

THEORY AND PRACTICE.

MR. CARPENTER ON GASEOUS FIRING.

SIR,—After Mr. Hunt's recent remarks (*ante* pp. 28, 166) upon Mr. Carpenter's paper, on "The Principles of Gaseous Firing," read at the meeting of The Gas Institute in June last, I thought we were on the way towards ascertaining what we are very anxious to know—viz., the amount of fuel consumed for producing gas where the simple generator is employed, and the amount where the complete regenerator is used. After reading Mr. Carpenter's two papers—one at the Southern District Association, the other at the Institute—on this subject, together with the discussions on them, I have to confess that I have not been able to get from them one atom of reliable information as to the quantity of fuel actually used at the Vauxhall Gas-Works. The basis on which he founds his calculation is erroneous, starting, as it does, upon a loose and inaccurate assumption, and ending in a result even wider of the truth than the original assumption itself.

Your correspondent "A. B." evidently writes with only an imperfect understanding on the subject, or he would not try to make out that much more coke can be produced in the retort from a ton of coals in London than in Birmingham. Why does he endeavour to confuse us by writing about so many speculative level or heaped bushels of coke from a ton of coal? Surely he must be aware of the increase in bulk between the coal put into, and the coke drawn out of a retort, when the coal used comes from the Newcastle district, like that used by the South Metropolitan Company. This coal swells and increases materially in bulk during distillation; and the resulting coke is very porous, and capable of holding a great deal of absorbed moisture; whereas the coke yielded by the inland coal used in Birmingham is much more dense, and scarcely more bulky, than the coal from which it was produced. While the bulk of coke from a ton of coal in London may be greater than that from a ton as used in Birmingham, there cannot be much difference in the weight of this residual when drawn from the retort. It is the after manipulation that makes the difference in weight. It might be well if "A. B." would look into "Field's Analysis" for 1887, and say, if he can, how it is that The Gaslight and Coke Company make 43·7 bushels of coke from a ton of the same kind of coal as is used by the South Metropolitan Company, while the latter Company can produce 49·8 bushels. The Gaslight and Coke Company also use 8·8 bushels of their make for fuel, while the South Metropolitan Company use 9·9 bushels for the same purpose.

Mr. Carpenter, in his letter in the JOURNAL for the 31st ult. (p. 208), says: "After deducting the fuel value of the tar burnt, I sell 10·3 cwt. of coke for every ton of coal carbonized." There is nothing exceptional in this sale of Newcastle coke; and no doubt the same amount is being disposed of at other works where neither generator nor regenerator furnaces are employed. In fact, Mr. Frank Livesey informed the members of the Southern District Association of Gas Managers, before whom Mr. Carpenter read his first paper, that he had made a series of experiments to discover the average weight of coke produced from a ton of the coal they used, with the result that 15 cwt. of coke was, on the average, obtained in the condition in which it was sold to the public; and in one case it reached as high as 16 cwt. At the same meeting Mr. Livesey said that with a good setting of retorts he was selling 10½ cwt. of coke per ton of coal carbonized. According to this, 4½ cwt. would be used in the furnaces as fuel for heating the retorts. From Mr. Carpenter's own showing, he has only produced 10,250 cubic feet of gas per ton of coal, or 6000 cubic feet per mouthpiece, and has sold 10½ cwt. of coke. Taking Mr. Livesey's own figure for the make of coke, this leaves 4½ cwt. for fuel, or 21 lbs. of coke for every 100 lbs. of coal carbonized, which is practically the same the quantity used by Mr. Hack at Salfrey before the introduction of furnaces of the regenerative type. If Mr. Carpenter will look again at "Field's Analysis," from which he quotes, he will see that several works in his district are doing much

* As remarked in the first article on "Gasholder Guide-Framing," the wind pressure increases as you rise from the ground (see "Graham's Graphical Statics"); but this does not affect the question at issue. It would be impossible to treat of gasholders under every possible condition of wind pressure—local gusts, protection by surrounding buildings, &c. The only reasonable course is to adopt a sufficiently high maximum pressure per square foot to cover all these little irregularities, and take it as uniformly loaded.

better than he is, without either generators or regenerators. By handling the "Analysis," Mr. Carpenter shows that he sells 2 cwt. of coke per ton more than they do in Birmingham; but by a further calculation he might just as easily have shown that the South Metropolitan Company are actually credited with selling more coke per ton of coal than they make from the same weight in Birmingham. Mr. Field assumes a chaldron of coke to weigh $9\frac{1}{2}$ cwt., or 32½ lbs. per bushel. In another place he states that the South Metropolitan Company make 49·8 bushels, and use 9·9 bushels, or sell 39·9—say 40 bushels per ton of coal; therefore they sell 1300 lbs. per ton of coal. The make of coke at Birmingham is recorded as being 1230 lbs. per ton of coal carbonized, or 70 lbs. less than the sale in London. Surely it is time that practical men gave up their unreliable and intrinsically inaccurate basis of assumption for a method by which the data in these elaborate analyses may be made valuable and consistent, so that the simple, but important, matter of fuel used for heating purposes could be arrived at with a reasonable degree of certainty for any works.

So far as I can gather, Mr. Carpenter has not on any occasion, in print, given any data of value upon the fuel account, although he has been asked by Mr. Hack and others to do so. Why does he not take up the commendable position assumed by every truly scientific investigator, and give that easily obtained and indisputably accurate information about his furnace for which Mr. Hack asked at The Gas Institute meeting? Mr. Hack said (and his words commend themselves to everybody): "It is no use to say you sold so many chaldrons of coke, when you only sold so many before, and to claim the difference as the economy effected. There should be careful tests of the fuel used, weighed into the furnace; the coal put into the retorts being also weighed. In this way they could tell clearly and positively what the advantages were, in the matter of fuel of one kind of furnace over another."

There is no doubt that the furnaces at the Vauxhall works are simple in construction; but there is nothing new or novel about them. They are very similar, especially in the settings, to Herr Oechelhäuser's generator settings (illustrated in "King's Treatise," Vol. I., pp. 233-4); but since the furnaces there shown were designed, very great progress has been made with regenerator furnaces, which, when properly handled, produce a larger yield of gas per ton of coal and per retort, with a consumption of about 10 lbs. of coke per 100 lbs. of coal carbonized.

In conclusion, it appears to me that we shall require different proof than that which can be obtained by manipulating any sale account, based upon an assumed make of coke, before we decide to leave the indisputably more scientific regenerative furnace to go back on our footsteps for a whole decade, under Mr. Carpenter's leadership, to find a model upon which to found the only perfect retort-heating apparatus.

Aug. 13, 1888.

"JOCELYN CRUIKSHANK."

LAYING MAINS OVER RAILWAY BRIDGES.

SIR.—This is a matter of very common occurrence. Public roads are in no cases vested in railway companies, but in some local authority; and no gas or water company need be told that, on giving proper notice to the authorities, they can lay mains without their consent. It is absurd, then, to suppose that they cannot lay mains therein without the sanction of any railway company who may happen to have a bridge under the road.

Section 18 of the Railways Clauses Consolidation Act, 1845, to which you refer, begins as you put it: "It shall be lawful for the company, for the purpose of constructing their railway, to raise, sink, &c." These and many other powers, very arbitrary in themselves, but very necessary, are given to railway companies for the purpose of construction, but for that only. There is, however, this to be considered: Under the Railways Clauses Consolidation Act, section 45, it is provided "that such bridge, with the immediate approaches, and all other necessary works connected therewith, shall be executed and at all times thereafter maintained at the expense of the company." And in every railway Special Act where such powers are given, the steepest gradients of the road on each side of the bridge, and the minimum depth of soil over the bridge, are strictly prescribed; and it may be that the depth of soil is not sufficient for laying a large main. It is therefore expedient for the gas or water company's own protection, even though it may not be absolutely necessary, to arrange matters with the railway company before interfering with that part of the road which they are required to "maintain."

Gas Companies' Association,

76, Palace Chambers, S.W., Aug. 20, 1888.

W. LIVESEY.

EXTENSION OF THE BRIGHOUSE GAS-WORKS.—At the last meeting of the Brighthouse Local Board, the Clerk reported that the Local Government Board have acceded to the Board's application to borrow £1500 for the purposes of their gas undertaking.

MUNICIPAL CORPORATIONS (LOCAL BILLS), IRELAND, BILL.—This Bill, which is to enable Municipal Corporations in Ireland to apply municipal funds in the promotion of Local Bills in Parliament, was read the third time in the House of Lords on the 11th inst., and received the Royal Assent on the following Monday.

SCARBOROUGH GAS COMPANY.—The half-yearly meeting of this Company was held on Saturday, the 11th inst. Alderman Fowler presided; and, in moving the adoption of the report (a summary of which has already appeared), said that the Directors were able to pay the maximum dividend and to carry forward a balance of £834 18s. 2d. They had been enabled to reduce the price of gas to 2s. 9d. per 1000 cubic feet to private consumers, and to 2s. 8d. to the Corporation, which meant a loss of nearly £1800 upon the revenue. Mr. R. H. Butterworth seconded the motion. The report was adopted without dissent; and the maximum dividends were declared. Mr. G. Gascoigne (Chairman of the Derby Gas-Works) proposed a resolution that, in view of the decisive progress of the Company in recent years, its greatly improved position and efficiency, entailing as it had done greatly increased demands upon the time and attention of the management, the amount of remuneration to be paid to the Directors for the current half year should be £150, and a similar sum for each succeeding half year in which the maximum dividend should be paid to the shareholders. Mr. Robson seconded the motion; but the Chairman stated that the Directors did not wish such extra acknowledgment of their services. Ultimately it was resolved that £200 be placed at the disposal of the Directors as remuneration for their services in the current year. A vote of thanks having been accorded to the Chairman and other Directors, the proceedings closed.

Legal Intelligence.

GLAMORGANSHIRE ASSIZES.—FRIDAY, AUG. 10.

(Before Mr. Justice FIELD.)

THE SWANSEA CORPORATION AND THE SUPPLY OF COMPENSATION WATER.

An action was commenced to-day by Mr. E. Chrimes and others, trading as the Groesnant Tin-Plate Company, against the Corporation of Swansea, for the recovery of £2410, made up as follows:—£755 for penalties for the stoppage of compensation water from the River Lliw, 151 days at £5 per day; £755 for the like with respect to the Blaenant Ddn Brook; and £900 damages. The plaintiffs are riparian owners on the Lliw and the Blaenant Ddn Brook, and, as such, are interested in their waters.

Mr. M'INTYRE, Q.C., and Mr. VILLIERS MEAGER appeared for the plaintiffs; Mr. BOWEN ROWLANDS, Q.C., M.P., and Mr. DAVID LEWIS defended.

It was admitted, on behalf of the defendants, that the water was not sent down on the dates named by the plaintiffs, and that such stoppage did not occur in consequence of "inevitable accident" or the "act of God." For the plaintiffs it was argued that the omission of the Corporation to send down water was to suit their own purposes only, and was contrary to their Act of Parliament.

The arguments had not concluded when the Court rose.

SATURDAY, AUG. 11.

On the resumption of the proceedings to-day,

His LORDSHIP threw out a suggestion that the case might be settled by the parties.

After some consultation, the leading Counsel on each side retired. On returning, they said the agreement came to was that the claim for penalties in the action should be withdrawn—the defendants withdrawing the plea of the Public Health Act of 1875 for the purposes of that action only; the damages to be assessed by an arbitrator, if the parties were unable to agree upon them, and plaintiffs to have their costs.

Justice FIELD said this was a very reasonable agreement, and met the whole of the case. On the one hand, the mill-owners got no more than they were fairly entitled to, and the Corporation, on the other hand, were not made liable for more than they ought to pay. It was an honest and reasonable agreement; and he was glad his intervention had succeeded in bringing it about.

WESTMINSTER POLICE COURT.—WEDNESDAY, AUG. 15.

(Before Mr. BIRON.)

GAS CONSUMERS AND THEIR CONTRACTS.

To-day Mr. R. Darbyshire, of Oxford Terrace, Teddington, appeared to an adjourned summons, taken out at the instance of Mr. Arthur Dove, who claimed on behalf of The Gaslight and Coke Company a sum of £2 8s. 6d. for gas consumed at a house in Charlwood Street, Pimlico, from March, 1887, to January, 1888.

Mr. Dove said that, although the defendant had not himself consumed the gas, he was the person with whom the Company entered into an agreement, and therefore he was liable.

Defendant stated that in December, 1885, he went to the office of the Company, and gave notice that he was leaving the house, and that the supply of gas could be discontinued. The tenant who came after him apparently was not required to sign a fresh contract; and, after paying for two years, he got into difficulties, and left in debt. The Company accepted him as their customer, received money from him, and now he had gone away in their debt, and they would not take the trouble to find him.

Mr. Dove: We never recognized him, and the accounts have always been sent in in your name.

Defendant: And I have never been in the place since January, 1885.

Mrs. Darbyshire deposed that, in consequence of the verbal notice given by her husband, an official was sent two days afterwards to take away the meter and to disconnect the supply. She suggested the advisability of leaving it for the incoming tenant, as an act of kindness, and with a view of saving him expense. The man, on learning that the gas would be required, did not cut it off or take the meter away.

Mr. Dove denied that notice of any kind had been given by defendant, and urged that the contract Mr. Darbyshire entered into had never been terminated.

Mr. BIRON told the defendant that the contract he signed required him to give written notice to terminate it. Until such notice in writing was given, he was liable for all gas consumed.

Defendant said he thought the contract note he signed was only a matter of form. Certainly, he had no idea of liability for years after he left the house.

Mr. BIRON: When you sign a document again which imposes a liability, you will perhaps recollect the terms of it.

An order was made on the defendant to pay the money.

EXTENSION OF THE ILKESTON GAS-WORKS.—At the quarterly meeting of the Ilkeston Town Council last Tuesday, the Town Clerk read a letter from the Local Government Board with respect to the report made by Major-General Carey, after the inquiry held by him with reference to the application of the Council for sanction to borrow £6000 for works of gas supply. It appeared from the report that, although the scheme included six additional purifiers, it was intended to provide only two at present; and the omission reduced the amount to £4080, the loan of which the Board sanctioned for a term of 20 years. He added that, in compliance with the request of the Committee, he had written to the Local Government Board, asking for an extension of the time allowed for repayment to 50 years; and read a reply to the effect that such request could not be granted.

THE CARDIFF WATER-WORKS.—On Friday, the 10th inst., the members of the Water Committee of the Cardiff Corporation, accompanied by several of the Council, visited the water-works. The party first proceeded to Bly, where the machinery which has been erected for the purpose of pumping the water from the wells or springs in the district, and which it was explained by the Water Engineer (Mr. J. A. B. Williams, M. Inst. C.E.) was capable of raising 2 million gallons per day. Last summer these wells were of great value; yielding as much as 500,000 gallons of water per day in the driest part of the season—thus saving Cardiff from a water famine. The new works at Rhubina, where a balancing reservoir has been constructed, in which the water from the Taff Fawr is received, filtered, and then diverted to Llanishen, were inspected. The reservoir is situated at an altitude which will enable the Corporation, whenever they deem the time opportune, to supply Whitechapel, Llandaff, Penarth, and the higher parts of Penylan by a system of gravitation. Only one filter-bed has been constructed; but it is intended eventually to lay down four beds, with the accompanying pure water reservoirs. These will be capable of dealing with 1 million gallons of water per day. From Rhubina the party drove to the Llanishen reservoirs, where luncheon was served.

THE ARTESIAN WELL AT GAINSBOROUGH.—Last Wednesday, the members of the Gainsborough Local Board attended at the water-works for the purpose of testing the yield of the artesian well they have been sinking during the past two years. The boring has reached 1200 feet, 476 of which pass beyond the base of the marls, and into the Bunter sandstone. During last September the well was tested, when the yield was 5000 gallons per hour; and the quality was variously reported upon by several analysts. Since then an extension of 100 feet has been carried out; and the pumping has been going on for 16 days and nights continuously. It ceased on Wednesday, when a test was taken by means of a 1000-gallon tank. The yield showed a trifling increase; 8 min. 50 sec. being the time taken by the pump to lift 1000 gallons. The actual yield of water, making every possible allowance, is 6765 gallons per hour, or one-fourth of the actual quantity now pumped for the town's use from the River Trent. Several samples were taken for purposes of analysis, as, although the quantity is so much below what was anticipated, the quality of what has been obtained is very questionable; being of a high degree of hardness, caused, the analysts say, by the presence of sulphate of lime. Great disappointment is felt throughout the town, as already a sum of £5000 has been spent, apparently to no purpose. The boring—the only one of the kind in the district—has been watched with much interest by geologists and engineers from all parts of the country. The Local Government Board, acting upon the advice of Sir R. Rawlinson, refused some time ago to sanction any further loans for the purpose; and the latter portion of the cost has been met directly out of the district rates.

THE PRICE OF GAS AT BIRKENSHAW.—At the meeting of the Birkenshaw Local Board last Thursday, a letter was read from the Gomersal Gas Company, stating that the Directors had decided to meet the request of the deputation which recently waited upon them, and to make a reduction in the price of gas to the smallest consumers of a further 3d. per 1000 cubic feet, or 3s. 3d. net; a reduction of 3d. per 1000 cubic feet to consumers of quantities between 100,000 and 500,000 cubic feet, or 3s. net; and for quantities ranging from 500,000 to 1,000,000 cubic feet the price would be 2s. 9d. net. A letter from the Drighlington and Gildersome Gas Company stated that their price was 2s. 6d. per 1000 cubic feet, with discount according to consumption. The Board decided to discuss the question in Committee.

EASTBOURNE GAS COMPANY.—The report of the Directors of this Company, to be presented at the half-yearly meeting on the 27th inst., states that there is a net profit for the six months ending in June last of £4556 12s. 8d.; and deducting therefrom the sum of £18 17s. 6d. paid for interest, there remains £4537 15s. 2d., which, added to £2403 18s. 3d. (the balance brought forward, after payment of the interim dividend in March last), will give a total of £6941 13s. 5d. available for division. The Directors recommend that a dividend for the past six months be declared, at the rate of 12½ per cent. per annum on the £20,000 original capital of the Company, and also on the £12,490 (the amount raised on the "C" shares), and at the rate of 9½ per cent. upon the £55,000 paid-up capital raised on the "B" shares. This will absorb £4517 7s. 6d., and leave a balance of £2424 6s. 11d. to be carried forward.

Miscellaneous News.

SOUTH METROPOLITAN GAS COMPANY.

The Ordinary Half-Yearly General Meeting of this Company was held last Wednesday, at the Bridge House Hotel, London Bridge—Mr. GEORGE LIVESLEY in the chair.

The SECRETARY (Mr. Frank Bnsh) read the notice convening the meeting; and the Directors' report and the statement of accounts were taken as read (see *ante*, pp. 252, 296, 298).

The CHAIRMAN: Ladies and Gentlemen,—I always begin with the intention of making a short speech; and to-day I think that that intention will be carried out, for I have very little indeed to say. But in moving the adoption of the report, it is necessary that I should make a few remarks. The first observation I will make is as to the increase in the Company's business, which you are told amounts to 4·7 per cent. in the half year. Well, now, this increase depends to a considerable extent on the character of the weather, or rather on the thermometer. Taking last half year, the month of January was a mild one; and we actually sent out considerably less gas than we did in January in the previous year. The same may also be said of the month of May. In the other four months, however, there was an increase, particularly in June; and to give you some idea of the effect of the thermometer on the consumption of gas, I may state that in the nine weeks, beginning on the 2nd of June, and ending on the 4th of August, the increased consumption amounted to 14 per cent. over what it was in the corresponding nine weeks of last year. It is therefore not satisfactory to take a single half year, and base conclusions upon it. We have often said—and our experience justifies it—that reductions in price tend to increased consumption. Taking the last three corresponding half years, we find that in the June half of 1886, there was an increase of 9 per cent., which was a very heavy increase; in the June half of 1887, there was an increase of a little more than 5 per cent.—5½ per cent.; and then in the half year we are now dealing with, there was an increase of 4½ per cent. I think, therefore, that this at any rate is satisfactory, and is a justification for the policy the Directors have pursued in reducing the price of gas, because our strength is in obtaining an increase of business. It would not be a good day for gas companies if we were to find our business standing still. With reference to the accounts, there is very little indeed to say about them. Coals have been slightly cheaper than in the corresponding period of last year. In 1887 coals cost us 11s. 2½d. per ton; and in 1888 they cost us 10s. 10½d.—a difference of 4d. per ton. The products have yielded rather better. Whereas in 1887 they yielded 6s. 3d. per ton of coal, in 1888 they have produced 7s. 4½d. per ton. There has been an improvement all round. Tar was at its lowest in 1887. It is rather better this year. Coke was also at its lowest last year; and it has been better. The same may be said of ammonia. While I am on the subject of tar, I may say that we have, as stated in the report, burned a considerable quantity as fuel, because we held in the first place that its fuel value was greater than its selling value; and in the next place that the market was glutted—that the supply exceeded the demand—and that the only way to produce a balance was to remove what was in excess, and use a proportion of it for our furnaces. I may state here that it has been found that tar is worth 1½d. a gallon to burn, and that people are ready to buy it in quantities for this purpose at that price. It may also be used very advantageously under steam-boilers (on the plan devised by Mr. J. L. Chapman, the Engineer of the Harrow Gas-Works); and if gas companies generally do not like to use it for heating their retorts, and would use it under their steam-boilers, they would do a great deal to remove the glut on the market. However, things are improving undoubtedly. The next paragraph in the report informs you that exhibitions have been held in our district, which is a very large one. In the case of a provincial gas company, it is sufficient to hire the Town Hall, and hold a single exhibition of gas apparatus; and this serves for the whole town and for the company. But it will give you an idea of the extent of our district, when I tell you that we have had as many as 24 of these exhibitions in various parts. We have hired public halls in different places; obtained a talented lecturer on cookery from Kensington; and have given free lectures on four consecutive days in the week—in the afternoon and evening. We have had gas-stoves exhibited; and the result has been that, whereas in the June half of last year we increased the number of our stoves in use by rather more than 400, this half year we increased the number by more than 1400. There is therefore apparently a clear gain of 1000 stoves as the result of these exhibitions. I am bound to say also, in connection with these exhibitions, that the officers of the Company have taken up the matter in the right spirit, and have shown the utmost zeal and ability in conducting them, and have thus contributed very largely to their success. The next paragraph deals with the coal dues; and in this connection, I think it is only right to tell you what action I took—in the first instance, on my own responsibility. I was on the Committee of manufacturers for opposing the renewal of the coal dues; and these gentlemen repeatedly said to me: "Whenever we urge that the coal duties should be abolished, we are met with the remark, 'If you abolish the duties, the £150,000 a year paid by the gas companies towards those duties will simply go into the pockets of the gas shareholders.'" They also said to me "If you can show that this will not be the case, and that the benefit will go to the consumers, a very strong reason will be given for abolishing the coal dues." Well, there were considerable efforts made to induce the Government to take up the matter, and support the Bill that was promoted by the City Corporation and the Metropolitan Board of Works for the renewal of the dues next year. A deputation from them went to the First Lord of the Treasury, who promised to consider what they had stated, and to give them an answer in a few days. Seeing that it was a critical moment, I addressed a letter to the Right Hon. W. H. Smith, giving details showing the quantity of coal this Company used, what amount of coke we sold, and what would be the effect on the coke trade, and, moreover, that there would be a certain balance in hand when the coal dues were abolished. I then went on to say what we would do with this balance. I stated that there would be a saving of £15,000 a year, after allowing for an increase of the rates. Some people make a great deal of this point. They seem to think that if the money is not raised in one way, it must be raised in another; but I am not so sure about that. However, we pay £27,000 a year for the coal dues, which means a rate of 5s. in the pound; and no one says, or can prove, that the abolition of these dues will necessitate an increase in the rating of more than 2½d. in the pound. I said in my letter to Mr. Smith: "The saving of £15,000, coupled with the profit on the increase of business that will result from the reduction, justifies the announcement I made at the general meeting of the Company on the 22nd of February last, 'If the coal dues were not renewed, we should at once reduce the price of gas by 1d. per 1000 cubic feet.' Consequently, the consumers of gas and coke will obtain the full benefit of the non-renewal of the tax. But the reduction of 1d. in the price of gas will entitle the shareholders, under the

sliding scale, to ½ per cent. more dividend, or £5000 a year." Then I go on: "In my opinion, it will not be fair to the consumers to take this extra dividend, if earned, because the question of the abolition of the coal dues was not an element of consideration before Parliament when the initial price was fixed in 1876." This is my individual opinion. I know that, at the time the initial price was fixed in 1876, no one thought anything about the coal dues, which were then fixed up to 1889, or for thirteen years; and the matter was not considered at all. Therefore, if the coal dues are to be abolished, I feel it would be an act of justice to the public to let them have the full benefit; and moreover it would be an act of wisdom on our part to adopt this course, because I am quite sure it is detrimental to gas companies to appear too grasping in the matter of dividend. I do not know that I have anything more to say to you. I was going to finish with two or three remarks about the advantages of gas. Gas is unfashionable. We are constantly hearing people abusing gas; saying this, that, and the other about it. Though, however, they abuse it so strongly and object to it, still they use it; and they use it because there is nothing equal to it—there is nothing like it. I am not going to say that other lights may not for certain purposes be used with advantage. You may have a lamp on the table; and for reading purposes that, no doubt, is very fine indeed. But for general purposes of illumination, or for lighting rooms generally, a lamp on the table does not answer. Nothing will do it so well and effectively as gas; and moreover, the objection raised to the heat produced by gas is all in its favour. If there were no heat there could be no ventilation. That is the principle of Nature. The air which is so essential to us is kept in motion by the heat of the sun, and nothing else. It is the heat of the sun which is the prime mover; and the heat generated by gas in dwelling and other rooms may be used as the most effective means of ventilation—not merely to carry off its own products, but to carry off all the vitiated air of the room too. I have, therefore, the greatest confidence in saying that for general lighting purposes there is nothing like gas; and with the great improvements which have been made in burners of late years, whereby double the amount of light may be obtained for the same quantity of gas consumed, the advantages of gas are still further enhanced, because its price is practically reduced by improvement of the burners to about one-half what it otherwise would be. And then this enormous increase in the consumption which we find on the fall of the thermometer, is a very striking illustration of the use to which gas is put. We can only conclude that it arises partly from people lighting the gas to warm their rooms. In dull and cold weather, the days are shorter; but I believe a very large quantity of the increased consumption that we see is owing to the use of gas for heating. At the low price (2s. 5d.) at which this Company supplies it, gas is used I know very extensively for this object; and it is also employed for manufacturing purposes. To give you one illustration—for such a purpose as enamelling glass or iron, where a certain heat is required to fuse the material on the surface. In the case of stained glass, for instance, the operation used to be done in a furnace heated with coal or solid fuel; and it required 24 hours to work off a single charge. The oven had to be heated, then the material was put in, and left in till it was cool. Now, with a gas-heated furnace, the fire can always be kept up to the exact temperature required. The glass is put in on a small traveller; and instead of taking 24 hours to do the work, it is done in an hour. I was told by one manufacturer only a week ago, that he is making arrangements by which he will be able to burn off a tray of glass in seven minutes, instead of an hour, by simply providing another chamber for cooling it, and letting the fusing be done in this one. This is only an illustration of what is going on in numbers of other cases. Gas is being used for a multiplicity of purposes, of which you and I have no conception. All sorts of manufacturing work is now being accomplished by gas, instead of solid fuel; and when we look at all these sources from which our profits are derived, we need, I feel sure, have no fear in regard to the future. We may believe that the future is likely to be as prosperous as the past; we may expect an increase of business in the future; and this increase will enable us to reduce our price, which would still further consolidate our position, so that we, or our successors, will be able to render as good accounts to our shareholders in the future as we submit to day. I now move—"That the report and accounts now presented be received and adopted, and the report entered on the minutes."

Mr. ROBERT MORTON seconded the motion.

The CHAIRMAN, in answer to Mr. Bradfield, stated that the duty on coal was 1s. 1d. a ton, of which 9d. went to the Metropolitan Board of Works, and 4d. to the City Corporation.

Mr. RIDGE said he did not clearly understand how the dividend of 13 per cent. would be distributed.

The CHAIRMAN: It will be divided just as it was last half year between the "A," "B," and "C" stock.

Mr. G. BRAY said he was sorry he could not quite agree with the terms in the report in regard to the half year being "uneventful" and "satisfactory." There had been rumours during the last twelve months as to the unsatisfactory condition of the works at East Greenwich. The last half-yearly report stated that everything was in a satisfactory condition there. The Chairman also in his speech made the same announcement; and he would give the terms in order that there might be no mistake. First as to what was said by the Directors. Last half-year's report stated that "the Directors are pleased to be able to report that from the starting in August to the present time the working has gone on satisfactorily." Again it said: "The whole of these extensive works have been satisfactorily carried out under the supervision of the Company's Engineer, whose services the Directors fully appreciate and have suitably acknowledged." Then the Chairman, in his speech at the half-yearly meeting, referring to these works, said: "They are working very satisfactorily . . . and we are quite satisfied with the manner in which they have been carried out." Further on in his speech, he said: "When I was on the question of the new works, I might have said that there have been reports that we were in difficulties. Well, you may take it from me that we were not in any difficulties, and have been in no difficulties whatever with regard to these works." These were emphatic statements; but since they were made, a report had been presented by a Bolton Corporation Committee on the question of gas machinery stoking, and a deputation of the Corporation asked to be shown round the works at Greenwich, and permission was given to them. The report they gave of what they saw said—

Mr. G. HOWLETT rose to a point of order. He failed to see anything in the report as to the Greenwich works; and he asked if the honourable proprietor was in order in bringing forward anything that members of a provincial Corporation might have seen at these works.

The CHAIRMAN: You are not absolutely in order in alluding to the report of the Bolton Corporation; but if you have any remarks to make about the works, Mr. Bray, I have no objection to listen to them, and to give the best answer in my power; but the honourable proprietor is certainly right in suggesting that you are not in order.

Mr. BRAY said he was perfectly satisfied that, under the terms of the notice convening the meeting, he was in order. It stated that certain specified business would be transacted, and the meeting was called "for

other purposes." The "other" business was not in the hands of the Directors. The Bolton Corporation stated that they saw—

The CHAIRMAN: I cannot allow you to read that report. You may make a speech if you like; but you must not read that report, which has nothing to do with us.

Mr. BRAY (continuing) said that the report from the Bolton Corporation was to the effect that the works at Greenwich were sinking into the ground. (Ironical laughter.) He submitted that there was nothing to laugh at in connection with the condition in which the gentlemen to whom he was referring stated that they had found the works. The works, they said, were sinking into the ground; and an expensive machine stoker which they had gone to see was not, in consequence of the state of the works, in working order, and that stokers were doing the business by hand firing. If this statement was not true, it could be contradicted; and he would be glad to hear that the statement of the Bolton Corporation was not correct. He held, seeing that so much had been stated with respect to the efficiency of the Greenwich works, that sound and true information regarding them ought to have been submitted to the proprietors. He had an objection to take to the refusal of correct information by the Directors on another point. The proprietors were aware that a good deal had been said recently regarding the Amalgamation Schemes; and although nothing had been said in the present report as to amalgamation, it was freely discussed at the last meeting. He had information, which was not available at that time, which he thought it was necessary that the proprietors should be in possession of with respect to that matter. They might be aware that the last proposal was with regard to the amalgamation with The Gaslight and Coke Company. That proposal was made by the Chairman himself; and he was prepared to state that he was suspicious of those proposals, and he looked into the sum which the Directors had received in connection with the question of amalgamation. He found the amount; and he asked questions as to the sums certain Directors had received in connection with previous amalgamations. He found that there were sums amounting to £26,229 put down in the balance-sheet for December, 1882, and June to December, 1883, under the heading "Commutations under the Schemes;" but the Directors had refused to inform him to whom the £26,229 had been paid.

Mr. HOWLETT rose again to a point of order. The whole question of amalgamation had been settled for years past; and he objected to Mr. BRAY reiterating an old question of amalgamation, and wasting the time of the meeting in doing so. What Mr. BRAY's purpose was he could not say. He took it that at their half-yearly meetings they had to deal with business before them.

The CHAIRMAN: I am obliged to rule, much to my regret, as I should like to hear Mr. BRAY out, that he is entirely out of order in referring to an amalgamation which took place eight years ago.

Mr. BRAY observed that if the matter was not discussed at the meeting, it would not be allowed to remain where it was. He submitted that he was in order; and he now asked whether the Chairman—loud cries of "Chair, chair!"—whether the Chairman had received the sum in question, or any of it; and if so what for. Also if the proprietors voted upon it, and were allowed to know what the sums were for? Did the Chairman refuse to reply now?

Mr. HOWLETT said his remarks would be entirely confined to the half-yearly report. He thought, however—

Mr. BRAY (interrupting, and addressing the Chairman): I ask if you will refuse to give the information.

The CHAIRMAN: I will give my reply at the close of the discussion.

Mr. BRAY: It would be more convenient if you gave it now.

The CHAIRMAN: I shall not do that. I shall give my reply at the close.

Mr. HOWLETT assumed that the Chairman would conduct the meeting in the ordinary way; he was not aware that Mr. BRAY held any patent yet for conducting public meetings. For his own part, he had to compliment the Directors on the report they had brought forward. He was in a very different spirit from the last speaker, who seemed to have attended the meeting to air certain grievances that he might have with particular members of the Company. The proprietors as a body, however, were there as business men; and they had not come to listen to any private grievances. He had been to the Greenwich works, and had seen no part sinking. However, the Bolton Corporation might be very clever, and might have seen a good deal that other people did not see. It was the business of the proprietors to increase the prosperity of the Company rather than to be complaining and carping about what was being done at Greenwich. In his own case he illuminated his house with gas; he burnt it as fuel in every stove in his house; and he cut his chaff with a gas-engine; and last half year he tried to distribute a large quantity of coke among people who had not burnt it before. If every shareholder would take this view of the concern in which he was a partner, they would soon have a state of things even more pleasant than had been submitted to them that day. He was very pleased with the report. The Company had gone on with a series of uninterrupted successes; and he believed that if the business continued to be conducted in the same straightforward and honourable manner as in the past, further successes would come to the Company.

Mr. SUGG observed, with regard to the complaint of Mr. BRAY as to the East Greenwich works sinking, that he happened to be able to give the proprietors a different piece of information. Mr. BRAY stated that the Bolton Corporation had been to the works, and had seen them sinking into the ground. He (the speaker) had, however, been to the works with a company of the most distinguished French engineers and European engineers of the day. They went over all the works; and he could assure the meeting that their inspection was a very careful one. He heard no one say anything about the sinking into the ground. On the contrary, the French engineers said that it was the simplest and finest piece of construction they had ever seen anywhere; and their encomiums upon the works were very great indeed.

A SHAREHOLDER asked whether they got as many feet out of a ton of coal by using tar as they did by coke.

The CHAIRMAN: I will answer the last question first. There is more difficulty in keeping the heats regular by burning tar than there is by burning coke; and if the men do not look to them and give that constant attention to the tar fires which they require, you will not get quite so many feet per ton of coal as you do when burning coke. I do not know that there is any other question I have to answer. I have replied to the inquiry as to the dividend—that the dividend of 13 per cent. spoken of in the report means 13 per cent. dividend on the whole of the capital, which will be divided in accordance with the terms of the Scheme of Amalgamation of 1880; and the dividend will be exactly the same as it was last half year to all classes of shareholders. Now, as to the works at East Greenwich, Mr. BRAY, I think, said that "sound and true" information should have been given. I tell you, gentlemen, that true information has been given. I am not going to tell you that the Directors of this Company are such an incompetent body that they would proclaim aloud to the world everything connected with the management and working of the Company. There may be things not detrimental to the Company—I may say that most decidedly—but things not advantageous

to state in a public meeting, with reporters present; and we reserve our discretion as to what we tell you. But I repeat that sound and true information has been given to you, and I tell you that these works are in a good state; and that if any of the shareholders would like to see them, nothing would please me better than to take them over the works. They are working now as satisfactorily, if not more satisfactorily than any of our stations; and as to this unofficial and unauthorized report from which Mr. BRAY has quoted, that report has in his own paper been shown to be erroneous in many particulars by gentlemen who have written about it. I have also had a letter from the Chairman of the Bolton Gas Committee, expressing the very greatest regret that anything was said about the works. The other question which Mr. BRAY has asked has nothing to do with this meeting; but I feel bound to say a few words. Mr. BRAY was not a shareholder when the amalgamation took place. In fact, he became a shareholder on the 1st of April, 1886, and I tell you, gentlemen, that his object—which I know—in becoming a shareholder was solely, or mainly, for the purpose of attacking me.

Mr. BRAY, amid loud cries of "Order," said he denied the imputation.

Mr. REDFERN: The truth is unpalatable, Mr. Chairman.

Mr. BRAY said he absolutely denied the imputation. The Chairman could know nothing about his motives, in becoming a shareholder; and he asked him to withdraw what he had said.

The CHAIRMAN: I will withdraw, then, all imputations on your motives; and I will say that your acts and deeds performed since you became a shareholder have been conclusive to my mind, and to every reasonable mind, that that was your object. It is in connection with the Crystal Palace Exhibition. Mr. BRAY says an injury was done to him; but I am not going into this. I am perfectly prepared to answer every question shareholders may put when asked in the interests of the Company, and when it will be to the interests of the Company to answer it. As far as regards the personal question which Mr. BRAY has asked, I should like to answer it, because whatever I may have received has been with the sanction of the Board of Trade, the Public Auditor, and the shareholders too; and I am not ashamed of anything that I have received. That, however, is not a question that is before the meeting.

The resolution was then carried unanimously.

The DEPUTY-CHAIRMAN (Mr. J. Mews): I have to propose the resolution as to the dividend; and the motion is as follows:—"That a dividend at the rate of 13 per cent. per annum be now declared, and that such dividend (with the exception of the sum of £500) be apportioned among the three classes of stock as prescribed by the Scheme of Amalgamation, 1880, and that the warrants be transmitted to the registered addresses of the proprietors by post." There is nothing I need say in addition to what I have just read, as I think the affairs of the Company have been very fully considered, and explanations have been given by the Chairman on every possible point.

Mr. T. ROWLAND HILL seconded the motion, which was agreed to.

Mr. MACE then proposed a vote of thanks to the Chairman and Directors, for the able way in which they had conducted the business of the Company. He said he considered they had shown great ability in bringing the concern to the position it now occupied.

Mr. FRANKLIN, in seconding the motion, expressed regret at the attack which had been made on the Chairman. Every attention ought to be given to remarks of proprietors, if they wanted to make a statement as to anything that might be dark in the affairs of the Company; but the position taken by Mr. BRAY was evidently one which ought not to be countenanced by the meeting.

The motion having been carried,

The CHAIRMAN said: It is peculiarly gratifying to me, and I have no doubt it is to my brother Directors, to find this unanimous and hearty vote of thanks passed to us. I can assure you, on behalf of my colleagues as well as on my own behalf, that we really have the interests of the Company at heart; and you may rest assured that in every possible way we will endeavour to protect those interests, and to promote the prosperity of the Company. We have a good record to show in the past; and I do not think you have any reason to suppose that this record will show signs of being broken in the future. I am sure that you have in the Board a body of gentlemen who have a single-minded object in doing their duty to the Company and to the shareholders. And now I must say a few words as to the officers. We are indebted to them for very good work; and not merely good work. They do not simply do their duty, but they do it with earnestness, as if they loved the work. I can assure you that we are constantly finding that the various officers of the Company are endeavouring, by all the means in their power, to promote its prosperity, to economize in the working, and to increase the business; and I therefore think that a vote of thanks should be passed to them. I move—"That the best thanks of this meeting be given to the Engineer and the officers under him, and to the Secretary and officers under him, for their attention to their duties, and for the earnestness with which those duties were performed."

Mr. CHAMPTON seconded the motion, which was carried unanimously.

The CHIEF ENGINEER (Mr. Frank Livesey): Mr. Chairman, ladies, and gentlemen—I thank you very heartily for myself and all those included in the vote of thanks which you have so kindly passed in our favour. We are quite aware that we have not arrived at perfection; so that whatever merits there may be in the working results of the half year, we are still trying to do something better. In reference to our works at East Greenwich, I may say that they are now working at least as economically as any other station of the Company, and in the future we shall still go on improving there. We are building a second section there; and the work is being largely done by our own men.

The SECRETARY having briefly acknowledged the vote on behalf of himself and the staff working under him, the proceedings terminated.

WAKEFIELD GAS COMPANY.—The 83rd half-yearly meeting of this Company was held on Monday last week. Mr. W. Statter, Chairman of the Directors, presided, and moved the adoption of the report and statement of accounts, both of which were of a most satisfactory character. It was stated that the works are in first-rate order; and everything is going on as well as the Directors could expect or wish. The quantity of gas made during the past half year was 106,422,000 cubic feet—an increase on the corresponding half year of 3,119,000 cubic feet. The leakage was only 12½ per cent., as against 15 per cent. in previous half years; and although the Company are only bound to supply gas of 16-candle power, they have furnished it of 17½-candle power. The Company made upwards of 3,000,000 cubic feet more gas; but the extra cost was only about £41, and the cost of distribution is £53 less than a year ago. Their income is £816 more; for, besides the increase in the consumption of gas, they have received £582 more for residual products. The Chairman moved that a dividend of 11 per cent. should be paid on the original shares, and £8 5s. and £7 14s. on the new shares, all free of income-tax; that £1500 should be added to the reserve, so as to increase it to £9500; and that £414 17s. 2d. should be carried to the current half-year's account. This disposed of the profit for the half year, which amounted to £6772 14s. 8d. The report was adopted.

BARNET DISTRICT GAS AND WATER COMPANY.

The Half-Yearly General Meeting of this Company was held last Thursday, at the Guildhall Tavern, Gresham Street, E.C.—Mr. JAMES GLAISHER, F.R.S., in the chair.

The SECRETARY (Mr. Alfred Lass, F.C.A.) having read the notice convening the meeting,

The CHAIRMAN said that he met the shareholders that day under very painful circumstances indeed. As long as he (the Chairman) had been connected with the Company, Mr. Bontems had presided at every half-yearly meeting. He found his health failing him, and he had just resigned when that sad street accident happened. He was knocked down by a milk-cart, which caused concussion of the brain; and under these painful circumstances they were parted. Little did they think, the last time they were there (although some of them thought he looked very ill), that they were soon to part, and under such painful circumstances. Their late Chairman was faithful. He told them at their last half-yearly meeting that in the preceding six months he had never omitted a single meeting of the Board, nor a single Committee meeting; and it was a fact. Then, with such extreme attention, to be removed, was something for which he (the Chairman) found it difficult to find words to express himself. He was certain that their deceased friend's wife and family had the deepest sympathy of the shareholders; and that the meeting would pass a vote of condolence with them. He would propose that a letter of condolence to the widow should be written by the Secretary, expressing their deep sorrow and pain at the circumstances under which their late Chairman was taken from them.

Mr. C. HORSLEY, J.P., seconded the proposal, which was at once acquiesced in by the shareholders.

It was agreed to take as read the Directors' report and the accounts for the past half year, an epitome of which was given in the JOURNAL last week (p. 306).

The CHAIRMAN said the first sentence in the report stated that, "in accordance with the agreement with the Barnet Rural Sanitary Authority, mains have been laid for the supply of water to South Mims village." He had been over this district; and when he saw the ponds from which a good deal of the domestic water had been taken by the villagers, and also the two pumps—requiring great labour (for the water was deep) to raise and then to carry it—he could not help thinking that, independent of anything else, it was a philanthropic piece of work to go there at all. He was also pleased with the manner in which the pipes had been laid. The next paragraph in the report spoke of the sinking of the new well. This was proceeding. It had been a long time about; but it was a heavy piece of work, and was imperatively necessary. They were now down 230 feet. The pumps had been fixed in position; and he hoped, in the present state of the work, that at the next half-yearly meeting the Board would be able to tell the shareholders that it was finished, and then this account would be closed. The business of the Company, the report stated, continued to increase. He would make a few remarks upon both the gas and the water undertakings with respect to this increase. Taking gas first, in the year 1878 they made 30,989,000 cubic feet of gas; and in 1887 they made 50,770,000 cubic feet—being an increase of 19,781,000 cubic feet in the nine years. In 1878 the revenue received was £8339; and last year £11,492—showing an increase of £3153 in nine years. Now, the price charged for gas in 1880 was 6s.; on the 3rd of April in that year they reduced it to 5s. 9d.; then on the 6th of June following they lowered it to 5s. 6d.; on the 5th of October of the same year they reduced it to 5s. 3d.; on the 5th of April, 1882, the price was brought down to 5s.; two years passed, and they reduced it to 4s. 9d.; on the 5th of January, 1885, they lowered it to 4s. 6d.; and on the 5th of April this year to 4s. 3d. Their experience was that they gained by every reduction they made. They had increased this year, with the price at 4s. 3d.; and the Board had determined that day to reduce the price to 4s. throughout the whole district as from Jan. 1 next. The Board hoped that this would give them an impetus. They wanted a fillip of some kind to improve the gas portion of the undertaking, for in the nine years the increase had been little more than 60 per cent.; and in ten years they ought to have doubled, as the price of gas was then 6s. Now that there was to be a greater reduction, he hoped they would have to speak in a few years of a greatly increased business. The capital employed in 1880 was £71,385; and in that year they only carbonized a ton of coal for £19 of capital. This was very bad. This year their capital was £83,338—being an increase of £11,953 in the eight years; but they had carbonized a ton of coal for £15 4s. of capital. In some of the largest works a ton of coal was carbonized for £5 of capital; but he could scarcely persuade himself that he should live to see it come down so low as this in their Company. However, the gas consumption was steadily increasing; and they hoped that it would increase at a more rapid rate in the future. There was one thing to be said. Last Thursday he went with their Engineer (Mr. Martin) over the pipes; and for two miles of pipes he found they had only three customers. They had only, on an average, 33 customers to a mile of piping; while the London Companies had more than 100 customers, and the Suburban Companies 57. Many of their (the Barnet Company's) customers were only small ones—not large ones like they were in London; so that the shareholders would see the difficulty they had to contend with. Their make per mile of main was only 1,238,000 cubic feet; in the Metropolitan districts the make was 8,442,000 cubic feet; and in the Suburban districts the average was 3,388,000 cubic feet. The shareholders would see what a great deal the Company had to do to pull up; but the greater the difficulty, the greater must be their perseverance. Turning to the water portion of the undertaking, in 1878 their rental was £1715; and last year it was £11,564. In the nine years, therefore, they had increased in their rental £6849, or 145 per cent. This was very satisfactory; and they had every reason to believe, from the steadiness of their progress during those years, that it would continue. The quantity of water pumped in June, 1880, was 101,600,000 gallons; in June, 1888, it had risen to 255,173,000 gallons. Thus in eight years it had increased by 153,573,000 gallons, or 151 per cent.—something more than the rental. The capital employed in 1880 was £73,603; in 1888, £119,441. The capital, therefore, in the eight years, had increased by £45,838; but when he went a little further, and asked himself what was the capital for every million gallons of water, he found that in 1880 it was £724; and the average of the London Water Companies was £240. In June last this £724 was reduced to £468 per million gallons. So that in these eight years they had made a very solid step downwards in this respect. Their consumers were their best friends; and ever since he had been on the Board, his constant object had been to consider the interests of their customers. Some of the water consumers were totally misled by the Company's Act of Parliament as to the meaning of "rateable value." There were residing in the Company's district some few consumers who were withholding payment for their water because they considered the charge to be based upon the poor-rate assessment. In the action recently brought against the Company by Mr. Stevens, it was decided in the Court of Queen's Bench that the poor-rate assessment was not the basis upon which this Company's charge for water should be made. He should like to say that if those consumers who considered that they had a grievance, because the Company declined to adopt the poor-rate assess-

ment as the basis of charge, would adopt the decision of the Judges upon this point, they would save themselves both trouble and expense. When the Company's Bill was passed, it was mentioned to be rack-rent; and considering that rack-rent was the basis, the charge was very low in proportion to what it would have been upon the poor-rate assessment. The Bill was considerably criticized in passing through both Houses of Parliament, and it was very evident that the consumers suffered loss and inconvenience by not attending to what the law is upon the subject. They were prospering very rapidly in both branches of their business; and he did hope that, as they were now supplying 250 cubic feet of gas for 1s., many more people would use it in the future than had done in the past. It was the best, and he thought the most healthful illuminant. At all events, they would look forward hopefully. He begged to move—"That the report of the Directors, together with the balance-sheet as signed by the Auditors be received, adopted, and entered upon the minutes."

Mr. HORSLEY seconded the motion.

Mr. F. WAKEFIELD, referring to the demise of Mr. Bontems, said he did not think this gentleman could have had a single enemy in the world, because any one more courteous or pleasing to talk to he had never met; and the shareholders could, he thought, all bear witness that no one could act better or more honestly in the chair than did their late friend. As representing one of the largest consumers, and in his private capacity, he could find no fault with the charges the Company made for gas. The Board had set a very good example to the other Gas Companies who supplied Finchley. In regard to the fight which Mr. Stevens had had with the Company, personally he was very glad he had not succeeded, and that the verdict had gone the other way—especially considering the position of the Company. As the Chairman had shown, they could not be compared with the London Water Companies, as in their own case they extended their mains into districts where they obtained very little revenue. Alluding to the dividend proposed, he said he thought it was about time they had a little more return for their money. They had now had 7 per cent. for a long time. Many gas companies he knew would consider 7 per cent. rather a poor thing; in fact, there were few of the Suburban Companies which were paying so little as the Barnet. Perhaps he might suggest to the Directors that they should now turn their attention to getting a little more dividend, and not do any more "philanthropic" work at present. Referring to the proposal to light the streets at Barnet with the electric light, he said they were also going to inquire into the matter at Finchley; but in his opinion the electric light could not touch gas in point of price, either for ordinary house or public lighting.

Mr. LONDON inquired whether the letting out of stoves was progressing. He referred to the lectures in cookery which had been delivered in the South Metropolitan Gas Company's district, and he thought that if something of the same kind was carried out in the Barnet district, it would conduce to a more general adoption of cooking-stoves.

The CHAIRMAN, replying to Mr. Wakefield, said the Directors were with him as to what he had said with respect to an increase of dividend. As soon as they possibly could, they would raise it. They must, however, bear in mind that a few thousand pounds of undivided balance was all they had for a reserve fund; and they had no emergency fund. They had besides only 33 customers per mile of main. With respect to the adoption of the electric light in Barnet, he had no fear of it, as a great deal more money would have to be paid for it. As to the remarks of Mr. London, he said the Board looked forward to the 4s. price developing the use of gas for heating and cooking purposes. Mr. Magnus Ohren said that a price of 6s. per 1000 feet would pay in cooking; so the 4s. was well within the mark.

The motion was then unanimously carried.

On the motion of the CHAIRMAN, seconded by Mr. WAKEFIELD, dividends were declared at the rates of 7 per cent. per annum on the "A" and "C" stocks; 6 per cent. per annum on the "B" stock; and £4 18s. per cent. per annum on the "D" capital (water), all less income-tax, and payable on the 15th of September.

The CHAIRMAN, in proposing a vote of thanks to the officers of the Company, specially eulogized the services of the Secretary (Mr. Lass), the Engineer (Mr. Martin), the Chief Cashier (Mr. Wright), and the Auditors (Messrs. F. Lennard and A. G. Hounsham).

Mr. HORSLEY seconded the motion, which was unanimously approved.

A vote of thanks to the Chairman and Directors concluded the business of the meeting.

TOTTENHAM AND EDMONTON GAS COMPANY.

The report and statement of accounts for the six months ending June 30 last, which the Directors of the above-named Company will present to the shareholders next Saturday, are of a satisfactory character. There was an increase to the extent of 8 per cent. in the sale of gas, as compared with the corresponding period of last year. This continued increase has enabled the Directors to reduce the price of gas, as from the 1st ult., 2d. per 1000 cubic feet to private consumers, and lower the charge to the Local Authorities for the public lighting by 2s. 6d. per lamp per annum. The sale of residuals shows an improved value, with the exception of tar, which continues very low. The Directors have made a considerable outlay in improving the supply of gas at Winchmore Hill and in the western part of the Company's district, to meet a continually increasing demand. The Engineer (Mr. W. H. H. Broadberry) reports the works to be in excellent condition, and the quality of the gas satisfactory. The profit and loss account, inclusive of £3542 1s. 2d. brought forward, gives an available balance of £9235 7s. 6d., from which the Directors recommend the payment of the following dividends (less income-tax):—On the original capital at the rate of 11 per cent. per annum; and on the new ordinary capital at the rate of 8 per cent. per annum—amounting together to £5545 15s. 9d., and leaving a balance of £3689 11s. 9d. to be carried forward. The quantity of coal and cannel carbonized in the past half year was 12,525 tons; and 123,441,100 cubic feet of gas were sold. The residuals produced were as follows:—Coke, 7760 tons; breeze, 1213 chaldrons; tar, 125,245 gallons; ammoniacal liquor, 3062 butts of 108 gallons each, which was worked up into 103½ tons of sulphate. The total amount of paid-up capital on June 30 last was £150,000; but as the expenditure has been £153,661, this account has been overdrawn to the extent of £3661.

THE GAS SUPPLY OF THE CITY OF LONDON.—Professor A. W. Williamson, F.R.S., the Chief Gas Examiner for the Metropolis, has reported to the Corporation the results of the daily testings of the gas supplied by The Gaslight and Coke Company to the City of London testing-stations during the past quarter. He states that the average illuminating power in standard sperm candles was 16.5 at Jewry Street, 16.7 at Cloth Fair, and 16.8 at Salisbury Square; the parliamentary standard being 16 candles. At two of the stations the minimum lighting power of the gas was also higher than the requirements; but at Jewry Street it fell below the standard on four occasions during the quarter. As regards purity, sulphuretted hydrogen was not present in the gas last quarter. The proportions of sulphur in other forms than this per 100 cubic feet of gas averaged 11.5 grains at Jewry Street, 9.5 grains at Cloth Fair, and 9.6 grains at Salisbury Square. All these results were below the prescribed limit.

CROYDON COMMERCIAL GAS COMPANY.

The report of the Directors of this Company, to be presented to the shareholders at their half-yearly meeting to-morrow, states that the quantity of gas sold in the six months ending June 30 last showed an increase of 10,039,400 cubic feet, or 5·84 per cent., as compared with the corresponding period of 1887. The revenue from the sale of gas is, however, less by £593 17s. 8d., in consequence of the large reduction of 3d. per 1000 cubic feet made in the price. Increased amounts have been obtained for the coke and other residuals, with the exception of tar. A large number of gas cooking and heating stoves were supplied during the half year. The illuminating power and purity of the gas supplied by the Company have been reported as satisfactory by the gas examiner for the Corporation of Croydon. The unappropriated balance amounts to £16,570 6s. 9d., out of which the Directors recommend the payment of the standard dividends at the rate of 10 per cent. per annum on the capital of £51,600, and of 7 per cent. per annum on the capital of £137,500; and an additional dividend (under the sliding scale) at the rate of 3 per cent. per annum on the several classes of shares—all less income-tax—for the half year. The full dividends will absorb £10,229, and enable the Directors to carry to the credit of the next half-year's accounts the sum of £6341 6s. 9d. With regard to the works (which are under the supervision of Mr. J. W. Helps), there were 17,867 tons of coal and 262 tons of cannel carbonized during the half year; the quantity of gas made being 188,195,000 cubic feet. The residuals produced were: Coke, 217,560 cwt.; breeze, 1630 dozen 4-bushel sacks; tar, 179,929 gallons; ammoniacal liquor, 430,014 gallons; sulphate of ammonia, 175 tons.

BROMLEY GAS COMPANY.

The report of the Directors of this Company for the half year ending June 30 last, which, with the accounts, will be presented at the ordinary meeting of shareholders to be held on the 30th inst., states that the increase in the consumption of gas during the six months was somewhat disappointing, in view of the reduction in price (equal to about 7½ per cent.) which took effect from the 1st of January last; the amount of increase being only about 1½ million cubic feet, or 2½ per cent. Nevertheless, the half-yearly revenue account cannot, the Directors think, be deemed unsatisfactory; for, with the aid of the £458 1s. brought from the last account, it shows a balance of £5118 18s. 6d., available for division among the proprietors; of which sum the Directors recommend that £4573 should be applied in payment of dividends at the rate of 11 per cent. on the old capital and 8 per cent. on the new respectively, and that the balance—viz., £545 18s. 6d.—be carried to the next account. Owing to the reduction in the price of gas, which has lowered the half-year's gas-rental by nearly £800, the Company have barely earned the dividend recommended. The Directors, however, have confidence in the elasticity of the revenue, and believe that an increased consumption will, as on former occasions, result from the policy of liberality pursued towards the consumers; and that by the exercise of economy and careful management, they will be enabled to exhibit a still more satisfactory account at the end of the current half year. Since the last meeting the Directors have disposed of 315 shares by public tender, which realized £4921, representing an average price of £15 12s. 5d. per £10 share. These shares will participate, as from the 31st of March last, in the dividend to be declared at the forthcoming meeting. With regard to the works, the new gasholder is expected to be completed within a few weeks, and ready for use in the ensuing winter season. Thus ample storage for the Company's requirements for several years to come will have been provided. The Company's called-up capital amounted on June 30 last to £126,547, of which £117,048 had been expended.

MAIDSTONE GAS COMPANY.

The Annual General Meeting of this Company was held on Thursday, the 9th inst.—Mr. AMBROSE WARDE in the chair.

The report presented by the Directors showed that the profit for the year amounted to £8781, out of which they recommended the declaration of a dividend at the rate of 10½ per cent. per annum, free of income-tax. An interim dividend of 5 per cent. having been paid on the 1st of March last, the balance of 5½ per cent. would, if the recommendation were accepted, be payable on the 1st prox. The business of the Company continues to increase; and the works, plant, and mains have been kept in good condition by the Engineer and Manager (Mr. H. Smythe).

The CHAIRMAN, in moving the adoption of the report, said it was very short; but he wished to add to it, for the information of the proprietors, the fact that during the past year, for every ton of 20 cwt. of coal carbonized, they had sold 10,298 cubic feet of gas, and that its average illuminating power for the year had been 15·69 candles, and the sulphur compounds only 10·86 grains per 100 cubic feet, as testified by the Borough Analyst (Mr. Adams). The retort-house, where a Company must look to make their profit, was filled throughout with West's hand-power charging and drawing machines; and by the use of these and all modern appliances, the Company were again enabled to declare a dividend of 10½ per cent. per annum on the whole of the capital. At the same time they were supplying the consumers (whose interests were identical with their own) at 2s. 6d. per 1000 cubic feet. These results, he could assure the meeting, could not be obtained in the South of England, in an inland town like theirs, unless they employed the best apparatus, and conducted their business upon the most sound and economical principles; and he felt sure that they might safely anticipate a larger profit at the end of next year.

Mr. J. H. HILLS, seconded the motion, and it was carried.

The dividend recommended having been formally declared, the retiring Directors and Auditor were re-elected, and the proceedings closed with a vote of thanks to the Chairman and Directors.

THE WATER SUPPLY OF KIRKBY AND SKEGBY.—Last Thursday, Mr. Arnold Taylor held inquiries relative to applications made to the Local Government Board by the Local Authorities of Basford and Mansfield—by the former for sanction to borrow £6000 for the laying of mains, &c., for the supply of water from Sutton-in-Ashfield to East Kirkby, Kirkby-in-Ashfield, Todd's Row, Nuncargate, Annesley, and Annesley Woodhouse; and by the latter for permission to borrow £2700 for the purpose of supplying with water the contributory parish of Skegby, which includes Stanton Hill and Meden Bank. Objection was offered to the first-named scheme by Captain Salmond, a large colliery-owner in the parish; but his representative was not prepared to admit that the works were not needed. The scheme proposed by the Mansfield Sanitary Authority, which would cost £2700, was next considered; an alternative scheme, which could be carried out for £1028, being submitted by a private individual. The Inspector expressed his preference for the former. On the same occasion, the Inspector inquired into an application from the Sutton-in-Ashfield Local Board for sanction to borrow £1500 for the extension of the Sutton-in-Ashfield Water-Works system to Skegby and Kirkby-in-Ashfield. The various applications are now awaiting the decision of the Local Government Board.

NEWPORT (MON.) GAS COMPANY.

The Half-Yearly Meeting of this Company was held on Monday last week—Mr. E. J. PHILLIPS in the chair.

The SECRETARY (Mr. E. F. Marfleet) having read the notice convening the meeting, the Directors' report, with the accounts for the six months ending June 30 last, was presented. The latter showed the total share and loan capital to be £124,442 9s. 9d. The gross revenue for the past half year was £14,434 17s. 4d.; and the expenditure, £10,346 11s. 10d.—leaving a balance of £4088 5s. 6d. The amount of the dividend is £3800; so that there is nearly £300 more than is required for this purpose, but not more than is necessary to pay interest on debentures. In connection with the expenditure, it may be stated that a sum of £700 extra was paid in rates. The working was, however, a success on the whole.

The CHAIRMAN, in moving the adoption of the report, remarked, in regard to the increase in the item of rates and taxes—£982, as against £248 for the first half of last year—that it arose through a difference between the existing rating by the Assessment Committee and what the Company thought it should be. Had it not been for this, the half-year's earnings would have been sufficient to pay the dividend and interest. With regard to the extensions to Maindee, the Chairman stated that the supply had hitherto been divided as coming from the new and the old works. Henceforth, however, it would be from the new works. There was an application for an extension to Tydu. There was reason to think that Tredegar would light Lord Tredegar's house with gas; and this would be an encouragement. The engineering report as to the works showed that they were in good order. On the whole, much credit was due to the officials—to the Engineer (Mr. T. Canning, Assoc. M. Inst. C.E.), for the careful attention he had bestowed on the works and management generally, and also to the Secretary and other officers.

Mr. LAYBOURNE seconded the motion, and it was carried.

Dividends at the rates of 5, 3½, and 3½ per cent. on the various classes of stock were then declared, and the proceedings closed.

BRADFORD CORPORATION GAS SUPPLY.

At the Meeting of the Bradford Town Council last Tuesday, Alderman F. Priestman presented to the Council an account of the receipts and expenditure in connection with the gas supply of the borough for the six months ending June 30, 1888. He said there was a net profit of £5530 on the half year, as against £9070 in the corresponding period of 1887. It would be remembered that the period covered by the account was the one in which the reduction of 3d. per 1000 cubic feet in the price of gas was made, which reduction amounted in the aggregate to £6500. They had regained half of the loss which it was expected would be sustained by the reduction. The repairs to retorts had been much more extensive than in the corresponding half of 1887; the amount of expenditure being well on to £2000 more than in that period. There was, therefore, every reason to believe that the shortcoming would be made up in the current half year. The residuals had contributed very considerably to this result; and there was every prospect of its continuing to do so. In the statement he presented, almost everything spent on capital account had been placed to the revenue department, with the exception of £1800 for mains and services, £289 for stoves (on which the Corporation were receiving interest), and £150 laid out on works. The total sum expended by the Corporation up to the present time was £569,504; and the balance still unexpended was £20,306. The items of expenditure were so exactly similar to those of the first half of 1887, that he need not comment upon them. The bad debts were less than they had ever been in any other half year. At present they amounted to the extremely low sum of £155. In answer to a question, Alderman Priestman further stated that the price of coal was the same as last year, and that all the contracts made by the Corporation were placed with the proprietors of collieries, and not with coal merchants. The increased consumption of gas in the past six months was as nearly as possible 5 per cent. The amount received for gas was £58,136, as compared with £60,976 in the corresponding period of last year. The difference, it would be seen, was only £2800, in spite of the reduction in price.

EDINBURGH AND LEITH GAS COMMISSION.

A Meeting of the Edinburgh and Leith Gas Commission took place on Monday last week—the Lord Provost (Sir T. Clark) in the chair. After a discussion on the position of the Managers of the two gas-works in the possession of the Commission, the Clerk (Mr. J. M. Jack) read the following report by a Sub-Committee of the Works Committee on the transfer of the undertakings:—"The Clerk reported that he had had a meeting as to the Leith Company's inventory of stores, &c., with Mr. Beveridge (the Parliamentary Agent), who had advised that some items therein formed part of the going concern already bought and paid for by the Commissioners." He further read a telegram from Mr. Beveridge, stating that Mr. Ferguson, C.E., was of the same opinion; and he submitted a draft of a letter which he advised should be sent to Mr. Duncan. The Committee instructed the Clerk to despatch it, and also a similar one to Mr. Blair, if the Edinburgh Company's inventory appeared open to the same objection. The Committee remitted to Councillor Charles Robertson to check the inventories as far as possible; he getting the assistance of Mr. Blaikie and any further help he might find necessary." The report was adopted. The report of the Finance Committee was then considered; and the appointments therein recommended, of Mr. J. S. Gibb as Treasurer and Mr. Cockburn as Collector, were made. Mr. Colston, in order to get the business of the Commission "under weigh" as soon as possible, moved that it be remitted to the Works Committee to consider and report to the next meeting upon the proposed duties of Mr. Dewar, late Statutory Clerk of the Edinburgh and Leith Gas Company; that the Commissioners proceed at their next meeting to elect an Auditor; and that the next meeting of Commissioners be held on the 20th inst. Bailie Archibald urged that the Finance Committee should consider as to the reorganization of the whole staff. In future, he said, there would be one concern; and every official, with the exception of surveyors, &c., would require to have a certain district assigned to him. Mr. Colston said the regulations, &c., could be framed after these appointments had been made. It was likely that the Commission would obtain some information on the subject from the persons they had already appointed. Mr. Smith Clark suggested that Bailie Archibald should make a motion remitting the question to the Finance Committee for consideration and report. He said it appeared to him, having regard to the transactions which they had carried through, that it would be of vital importance that the accounts of the two systems should be kept as separate as was practicable. He thought it was also clear that the Commission must, as far as possible, use the officials as if they were conducting one system. At first this would give rise to some little difficulty as a mere matter of bookkeeping. They might, however, manage to apportion the cost of the officials common to both concerns—say, in proportion to the output of each concern. In whatever way the thing was to be managed, he apprehended that the time, if it had not already come, might arise when they would make a remit to the Finance Committee to consider the whole question, and to report to the Commission. The motion was agreed to.

DUMFRIES CORPORATION GAS SUPPLY.
ANNUAL REPORT.

From the report and statement of accounts issued by the Dumfries Gas Commissioners for the year ended May 15 last, we find that the gas undertaking has been in their charge for ten years; indeed, if we mistake not, Dumfries was the first town to take advantage of the provisions of the Burghs Gas Supply (Scotland) Act, 1876. This being so, a somewhat detailed notice of the undertaking in question, as it now presents itself in the annual report and financial statement, may have some interest for our readers, more especially those in the northern part of the kingdom.

During the year 5134 tons of coal were carbonized; being an increase of 55 tons over the amount consumed in the preceding year. The average cost was 14s. 11½d. per ton—a slightly lower average than that estimated at the beginning of the year by the Engineer (Mr. G. Malam). The quantity of gas manufactured was 51,442,700 cubic feet; the average yield per ton of coal being 10,020 feet. Including what was used at the works, the amount of gas sold was 44,531,100 feet; being an addition of 776,600 feet on the preceding year's sales, and an average of 8673 feet per ton of coal carbonized. The leakage or unaccounted-for gas was 13·43 per cent.—certainly a high rate; but considerably under what it was even less than ten years ago. New and larger street mains were laid during the year in certain portions of the area of supply, which, together with the ordinary renewals, involved an outlay of £424 12s. 9d., of which about one-third was charged against capital and the remainder against revenue. Where necessary renewals of meters were made at a cost of £28 7s. 8d.; and for new meters (not in place of old ones) an outlay of £67 14s. 6d. was incurred. A fresh contract for the sale of all the tar and liquor, at an increased price, was entered into for one year, as from the 15th of May last. The condensers erected last year have proved to be quite satisfactory as regards efficiency. Towards redemption of the new loan of £4000, the first payment of £231 6s. 5d., including interest, has been charged in the past year's accounts. Out of the said loan there were paid during the year various sums amounting in all to £2991 14s.—the largest items being £1822 8s. 5d. for land acquired, including law charges; £640 11s. 5d. for new condensers fitted up complete; and £290 as payments on account for new buildings and new boundary wall. After payment of £432 6s. 2d. on completion of the buildings and boundary wall, there will still be available for future extensions on capital account, a balance of £575 19s. 10d.

When the works passed into the hands of the Town Council in 1878, they had to be purchased by a loan, for which interest at the rate of 4½ per cent. had to be paid. On the 15th of May last, there was still owing on this loan the sum of £18,750. Another loan was contracted in 1885 at the same rate of interest; and on this the sum still owing is £3516 6s. 3d. Including the amount due on the loan of £4000 contracted during the past year, the total balance due on mortgages on May 15 was £26,194 19s. 10d. Up to May 15, 1887, the expenditure of the Gas Commissioners in the shape of loan capital (purchasing, improving, and extending works, &c.) amounted to £29,000; and as already mentioned, the expenditure during the past year was £2991 14s.—thus making a total outlay of £31,991 14s., with a balance on capital account of £1003 6s.

Coming to the revenue account, we find that the total cost for the manufacture of gas was £5625 12s. 9d., of which the chief item was £3832 6s. 11d. for the coal delivered on the works. Wages at works, including Engineer's salary, rank for £859 11s. 8d.; and repairs and maintenance of works and plant involved an outlay of £683 15s. For distribution of gas there was spent £326 11s. 5d. Rates, taxes, and insurance, management, law charges, &c., brought up the total expenditure to £6626 5s. 6d. From sales of gas, at 3s. 9d. per 1000 cubic feet, there was obtained a revenue of £8238 5s. 7d. For coke, tar, ammoniacal liquor, and refuse lime, there was obtained £624 4s. 10d. Rental from gas-cookers and other miscellaneous items brought up the total receipts to £8918 13s. 2d.; so that there was a gross balance on the year's operations of £2292 7s. 8d. carried to profit and loss account, the total amount of which on May 15 was £2305 13s. 5d. At the same date the reserve fund account stood at £398 16s. 6d., of which the sum of £150 was brought from profit and loss account. The sinking fund applied to the redemption of mortgages now stands at £943 3s. 11d. The balance of net profit to be carried forward is £17 2s. 11d.

In making out his estimates for the current year, the Engineer assumes that there will be an outlay of £3791 13s. 4d. for cannel coal and shale (5000 tons, at 15s. 2d. per ton); and in all, under the head of manufacture of gas, an outlay of £5516 13s. 4d. For distribution of gas the estimate is £323; for rates, taxes, and insurance, £146 0s. 6d.; management, £336 5s. These and other items are calculated to amount to £6496 18s. 10d. in the shape of total expenditure. It is estimated that the gas sales will amount to 43 million cubic feet; realizing (at 3s. 9d. per 1000 cubic feet) a sum of £8062 10s. The revenue from residual products is put down at £778 15s.; and the rental from gas-cookers and other miscellaneous items is calculated at £55. The total estimated revenue, therefore, is £8896 5s.; giving a prospective balance of £2399 6s. 2d. carried to profit and loss account, and a balance of net profit, on May 15, 1889, of £126 18s. 11d. This is after making full allowance for interest on mortgages, sinking and reserve funds, and working expenses, and crediting balance profit on the past year's working.

When the accounts were under the consideration of the Gas Commissioners at their last meeting, Provost Scott, in moving their adoption, said that they showed a profit in favour of the gas-works; but it did not warrant the Commissioners in interfering with the price of the gas. The charge was now 3s. 9d. per 1000 cubic feet, which he thought was a very moderate price. The estimates for next year showed a still larger balance in their favour. Mr. Currie, in seconding the motion, said that the improvements recently carried out at the gas-works had been fully justified. The motion was unanimously agreed to.

SKIPTON WATER SUPPLY.—Last Friday, a meeting of the Skipton Local Board was held—Mr. J. B. Dowhurst presiding—when a letter was read from Mr. Hill, C.E., of Manchester, giving particulars of the cost of bringing water from Cawder Gill into the existing reservoir, in iron pipes 15 inches in diameter (including contingencies); estimating it at about £2500. The laying of the pipes, he said, would no doubt give the town some relief for a few years to come; but he could not recommend the scheme except as an extension for tiding over the present deficiency. After a long discussion, a Committee was appointed to consult with various landowners as to other proposed schemes.

THE NORTHERN COAL TRADE.—There has been an improvement in the demand for both steam and gas coal in the North of England, and prices have advanced in some instances. Steam coal is now quoted at 7s. 9d. per ton for best qualities; and most of the collieries raising this class of coal have full employment, with, in some instances, pressing demand. Second-class coals are not in such full demand, and the larger output of small coals makes them weaker in price. Gas coals are generally in better demand; and there have been advances in price in the case of a few contracts which have just been renewed, whilst one or two local contracts are also in the market, and are expected to be closed at rather higher prices than the low rates which have ruled for a year. The demand for manufacturing coal is strong.

ARBROATH CORPORATION GAS SUPPLY.

THE PROPOSED EXTENSION OF THE GAS-WORKS.

At a Meeting of the Arbroath Gas Commission held on Monday last week, they had under consideration the question of the extension of the gas-works. A report on the subject by Mr. R. Mitchell, Engineer of the Edinburgh works of the Edinburgh and Leith Corporations' gas undertaking, was recently published in the JOURNAL (see ante, p. 132). The attention of the Commissioners was first directed to a letter which had been sent to the Clerk (Mr. D. Chapel) by Mr. G. Milne, a resident at Arbroath, drawing attention to the fact that a new illuminant, known as water gas, was being manufactured in several places in England, and enclosing for the information of the Corporation a copy of a report on the subject by the Leeds Forge Company, in whose premises the new system of lighting is being extensively used. According to the report, the gas possessed the virtue of being as powerful an illuminant as the electric light, and was producible at 4½d. per 1000 cubic feet.

Mr. DICKSON, referring to the subject of the extension of the gas-works, said he objected to the scheme on account of the enormous expense, considering the difficulty that would be experienced in satisfactorily supplying the lower parts of the town from the present site of the works. Even though the Commissioners might be satisfied that gas was the illuminant of the future, he for one should not go upon the principle of making improvements on a site which had been condemned by all the experts they had consulted. He thought they should consult gentlemen who were scientifically acquainted with other illuminants. He accordingly moved that the final decision of the Corporation should be delayed for six months.

Mr. SANDEMAN seconded the motion.

Provost ANDERSON said the Committee of Management had been quite unanimous regarding the necessity of the extensions; and he thought the Commissioners at their last meeting were unanimous that they should at once be proceeded with. (No, no.) He at any rate was so satisfied that they were doing the right thing, and saving money to the town, that there would be no increase of taxation, and that the price would not be advanced, that he moved as an amendment to Mr. Dickson's motion that the works should be proceeded with, and that it should be remitted to the Committee of Management to take in contracts in the terms of Mr. Mitchell's report, as qualified by the subsequent minute of the Committee of Management.

Mr. CARGILL seconded the amendment. It must be acknowledged, he said, that greater pressure was required throughout the town, and that this could not be obtained without increased storage accommodation. It had also to be borne in mind that gas might yet be improved as an illuminant; and that if any great step forward in its use were made, the community would be able to secure the benefit probably without great expense.

Provost ANDERSON remarked that the feasibility of changing the site of the works had been before the Committee of Management; but they had found that, from a financial standpoint, a removal of the works would be altogether impossible. To remove them would cost at least £20,000; and the only saving that would be effected would be some £300 per annum on cartage. The new works, therefore, would never recoup themselves; and, besides, they considered it too late in the day to talk of removing the works, after they had planted all their valuable machinery on the present site.

Mr. DICKSON said, with reference to the "valuable machinery on the present site" to which the Provost had alluded, they were just proposing to put down £8000 worth of new plant there. He pointed out, with respect to the other remarks of the Provost regarding the proposed alteration of the site of the works, that the £300 which they would save annually on cartage if the works were transferred represented £9000 of capital, which sum, with the £8000 they proposed spending under the scheme now being discussed, represented an amount almost equivalent to the estimated cost of removing the works.

The amendment was adopted by 8 to 6 votes.

Mr. MICHIE gave notice that at the next meeting he would move that they rescind the resolution, on the ground that several members of the Corporation were absent, and that it was arrived at by a narrow majority.

DENTON AND HAUGHTON LOCAL BOARD GAS SUPPLY.

The Manager of the Gas Department of the Denton and Haughton Local Board (Mr. James M. Veevers) has favoured us with a copy of the statement of accounts of the department for the year ending March 25 last, as passed by Messrs. Nairne, Son, and Pollitt, of Manchester. It is summarized in the following table; the figures for the previous financial year being given for comparison:—

	1887.	1888.
Cost of coal and cannel	£2476 8 4	£2289 0 0
Quantity used, in tons	4508	4475
Average price per ton	£0 11 0½	£0 10 2½
Total make of gas, in cubic feet	48,257,480	48,788,700
Total sale of gas, in cubic feet	42,527,344	42,810,023
Loss, in cubic feet	5,730,136	5,978,678
Loss per cent.	11·87	12·25
Gas made per ton, in cubic feet	10,700	10,927
Gas sold per ton, in cubic feet	9,493	9,566
Average illuminating power, candles	19·30	19·28
Income from gas	£6988 7 8	£6908 8 4
" meter hire	83 1 7	83 18 6
" tar and liquor	368 8 0	479 9 4
" coke	499 1 6	476 2 10
" sundries	140 17 2	23 19 1
Average cost of gas made per 1000 cubic feet	0 1 6½	0 1 5
Do. sold per 1000 cubic feet	0 1 9	0 1 7½
Average price of gas sold per 1000 cubic feet	0 3 3¼	0 3 2¼
Profit on gas sold per 1000 cubic feet	0 1 6½	0 1 7½
Annuities per 1000 feet of gas sold	0 0 8½	0 0 8½
Interest on loans, do.	0 0 9 5-7ths	0 0 8 1-5th

REDUCTIONS IN PRICE.—The Directors of the *Bilston Gas Company* have decided to reduce the price of gas by 3d. per 1000 cubic feet at the close of the present quarter.—The *Brighton and Hove General Gas Company* purpose reducing the price of gas by 2d. per 1000 cubic feet as from the 1st of January next.—The *British Gaslight Company* have given notice to their consumers at Hull that the price of gas will be reduced from 2s. to 1s. 11d. per 1000 cubic feet as from the 1st ult.—The Directors of the *Crystal Palace District Gas Company* have given notice that the price of gas will be reduced to 2s. 8d. per 1000 cubic feet from and after the date of the present Michaelmas quarter's accounts.—The Directors of the *Gloucester Gas Company* have decided to make a further reduction in the price of gas as from the end of last half year. The reduction will be 2d. per 1000 cubic feet. This will make the price 2s. 7d. per 1000, equal to 2s. 5½d. after the usual 5 per cent. discount is allowed. The price will even be lower than this to the Corporation for street lighting, as the 2s. 7d. is, under the contract, subject to a deduction of 10 per cent. and then to 5 per cent. off that. Large consumers are on the same terms as the Corporation.

THE PRICE OF GAS FOR PUBLIC LIGHTING AT SWANSEA.

At the Meeting of the Swansea Town Council last Wednesday, the Streets Committee reported that a letter from the Gas Company had been received stating that the Directors were prepared to continue the supply of gas to the public lamps, on the same conditions as the previous contract, at 2s. 10d. per 1000 cubic feet, such price to take effect on and from the 1st of October next. The Town Clerk was directed to inquire whether the "2s. 10d." was not a clerical error; the present cost of lighting being based on the price of 2s. 6d. per 1000 cubic feet. Mr. Richards, in moving the adoption of the minutes, said "the same conditions" seemed to mean an increase of 4d. per 1000 cubic feet. The Company wanted 2s. 10d. instead of 2s. 6d. This was, he supposed, whipping the Corporation because they had recently opposed the Company; for he was unable to see any other reason for such action. The matter had been referred to the Gas Committee; and he hoped something would be done in a short time to teach the Company that the Corporation would be able to do without them. The amount spent on public lighting was £3770. Mr. Martin said the Manager of the Company (Mr. Thornton Andrews, M. Inst. C.E.) had assured him that the increase was due to no ill-feeling; for though the price of gas to the Corporation had been raised to 2s. 10d., private consumers were charged 3s. Mr. Burnie said it was time the Corporation should look round determinedly with the object of seeing if a new method of lighting—electricity, for instance—could not now be introduced. There were electric lighting companies who would guarantee the street lighting for a less sum than that now paid. There was ample margin in £3770 a year to make it worth their while to consider the question of electricity. At a later stage in the proceedings, Mr. Martin stated that an offer had been made to the Council by a Company to light the town free, if the population was shown to be upwards of 80,000; the only condition being the use of a certain lamp.

THE MALVERN LINK LOCAL BOARD AND THE GAS COMPANY.

OIL TO BE ADOPTED FOR THE PUBLIC LIGHTING.

The question which has long been under discussion between the Malvern Link Gas Company and the Local Board, and which was thought to have been amicably settled a fortnight ago (see *ante*, p. 251), has been revived. It was further considered at a meeting of the Local Board on Monday last week. After the whole of the correspondence between the Board and the Company had been read, the Chairman (Mr. W. W. A. Tree) said he had taken into consideration the dates, the various letters written, and the meetings held by the Board, and the effect which they had upon his mind was that the Board had met the Company half way, and had tried to bring about an amicable settlement of this question. The Company made three alternative proposals—to supply the gas at 4s. 6d. per 1000 cubic feet, refer the matter to arbitration, or sell their works to the Board. The letter containing these proposals was considered at as early a date as possible; and the Board suggested certain conditions, which he thought might have been fairly accepted. For a month they did not receive any answer from the Company; and the Clerk to the Board was instructed to write them asking for a reply. To this they received a letter ignoring the conditions the Board had previously proposed. No attempt to discuss them in any way was made; but the Directors could not see the way to alter their conditions. Then the Secretary of the Company wrote on Aug. 1, stating that the Board had misconstrued his letter of April 7; the intention being that 4s. 6d. per 1000 feet should include the cost of lighting and extinguishing. Upon this the Board agreed to accept the Company's offer. A few days afterwards the shareholders of the Company held a meeting; and then the Secretary wrote to him to say that his letter of Aug. 1 was only a private suggestion, and that it had been rejected by the Directors and shareholders. If the Secretary erred in the construction of his own letter, it followed that the Directors wished to charge the Board £32 per season more than their official thought they intended to charge, and it might be reasonably inferred £32 more than he, the Secretary, considered they ought to charge. The Chairman moved the following resolution—"That the Clerk write to the Company, saying that as their letter of Aug. 1 is simply a repetition of proposals made on Aug. 7, which the Board have already rejected, they cannot entertain further negotiations with the Company." Mr. Webb seconded the motion, which was carried unanimously. A tender, in reply to the Board's advertisement for lighting the district with oil, had been received; and after a short discussion it was accepted—the Board stating that a saving of something like £109 per annum would be effected by the use of oil.

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON.

At the Meeting of the Leamington Town Council on Monday last week, the Mayor (Mr. J. Fell) in the chair—the following letter, dated the 31st ult., addressed to the Town Clerk by Mr. Arthur Chamberlain, on behalf of the Midland Electric Light and Power Company, Limited, on the subject of the electric lighting of the town, was read:—"We beg to acknowledge receipt of your favour of the 10th inst. (July), informing us that our letter of June 21 was considered by the Council, and that they have given permission for the erection of four arc lights, by way of an experiment, provided no charge be made on the Corporation, on some spot to be agreed upon, at a height not exceeding 50 feet, but that the Council object to the lights being placed on the Town Hall tower, as they considered the access undesirable, and the height (100 feet) far too great, and believe that a position facing the Parade would be more suitable. [See *ante*, p. 133.] The essence of our offer was that the arcs should be placed on the tower, and therefore in a position not absolutely facing the Parade, should be at least 100 feet high, and, though lent and fixed by us free of charge, should be connected to the present mains, and the current, therefore, paid for by the Corporation. We may take it, then, that the Council have given us permission to do as nearly as possible the exact opposite of what we offered to do. We do not call in question the wisdom of the Council in wishing to try the effect of four arc lamps of 2000-candle power each, placed not more than 50 feet high, and facing the Parade, which at its narrowest point is only 50 feet wide. We only say that we do not wish to try this particular effect a second time at our own expense. We have already, at our own expense, and on our own property, tried the effect of arcs between 30 feet and 50 feet high for street lighting. There is no mistake about the light. Used as we have shown in Wise Street, it would take the place of the ten street lamps. If the Council have not given attention to this particular illustration of the power of electricity as an illuminant, they can see it any night from nine till eleven. But this is an illustration of street lighting by arcs. What we last offered to do was to give the town an opportunity of seeing street lighting by incandescent lamps in combination with arc lighting of open spaces. The two are quite different problems. We think it extraordinary that so substantial and extensive a building as the Town Hall tower should only be available for the purpose of housing a clock; and we cannot understand how the man who attends to the arcs can do more damage to it than he who attends to the clock. But we accept the decision of the Council, and now withdraw our offer;

and we take the opportunity to withdraw also, at all events for the present, our former offer made some three months ago, to bear half the cost of removing the arms that now suspend the 16-candle power lamps from the posts, and to exchange them for upright lanterns and 32-candle power lamps. Our reasons are these: We find that our motives are not appreciated. We are supposed to be madly desirous for a continuance, at any cost, of our present contract for lighting the Parade; whereas, as a matter of business, we do not care about lighting the Parade at all. As far as the Parade is concerned, our chief desire was to assist the more public-spirited members of the Council in bringing Leamington abreast of the times. The system of lighting recommended by us, we admit—as discussed in full conclave, and adopted unanimously—does not appear, when in practice, to please the Council. This is a matter of taste, and not of electrical engineering. Still, we were willing to assist the Council in any change they desired; but every offer we made is used by our opponents as the excuse for some attack on our reputation, and some fresh outpourings of local spite and local prejudice. When we have been personally present, we have had no reason to complain of the result of the discussion; but behind our backs the matter is different. There, statements are made to our disadvantage that are unsupported by any evidence that would be received in a Court of Justice, and that are untrue in fact; and no effort is made to distinguish between legitimate criticism of matters of taste and opinion, such as the method of distributing the light and the appliances by which it is distributed, and for which matters the Council are now alone responsible, and the other matter for which only we are responsible—the candle power of the lamps. We ask—and surely it is not an unreasonable request—as a condition precedent of any fresh offer on our part, that the candle power of our lamps should be regularly tested and published at the same time and in the same way as the candle power of the gas-lamps is tested and published."

The Mayor said he thought it was a pity Mr. Chamberlain had not a wise man at his elbow when he sat down to write that letter.

Mr. CROWTHER DAVIES proposed that the letter be referred to the Watch Committee. He said it was such that, as a matter of taste, it was to be regretted that it had been written.

The motion was carried.

Mr. CROWTHER DAVIES had a motion on the *agenda* paper that notice be given to the Electric Light and Power Company to terminate the present contract in twelve months' time; but when this was reached, he asked permission to withdraw it. In doing so, he explained that it was his desire that no means should be left untried by way of arriving at a satisfactory settlement with Mr. Chamberlain. The desire of those with whom he was acting—and it was a feeling he shared—was that the Electric Lighting Company should not feel that any hasty steps had been taken by the Council to put an end to the contract, but, on the contrary, that every means had been used to bring about a satisfactory settlement. It was undoubtedly a most unfortunate letter they had heard read—unfortunate for the writer rather than the recipients. [A VOICE: "It's a very rude one."] He had formed a most unjust and unworthy conception of the Council as a whole, as well as of some of its individual members. The resolution he asked to withdraw was one he could carry; but as it was to be withdrawn, he hoped Mr. Chamberlain would come to the conclusion that it would be well to treat the Council as reasonable, just, and honourable men. There was no desire to "throw cold water" upon his Company; but to secure an arrangement which would be just to the rate-payers and fair to the Company.

Mr. BRIGHT said he thought Mr. Davies had acted most generously in withdrawing the motion. As one who advocated the introduction of the electric light, he certainly was not satisfied with it, but thought the defect was due, not to the light itself, but to the lanterns used. The letter sent by Mr. Chamberlain was extremely unwise.

Mr. DAVIES said he did not retract anything he had said about the light; and if it was not made satisfactory, he would revive the subject at some future time.

Leave to withdraw the motion was then given, and the subject referred to the General Purposes Committee.

METROPOLIS WATER SUPPLY.

According to the returns furnished to the Registrar-General by the London Water Companies, the average quantity of water supplied daily to the Metropolis in the past month was 169,387,002 gallons, as against 188,951,202 gallons in the corresponding month of 1887. The number of houses served last month was 740,236, or at the rate of 229 gallons per house, and 29.3 gallons per head of the population. In July, 1887, the number of houses was 727,543; and the quantity of water allowed for each person 33.3 gallons. Of the entire bulk of water supplied last month, 83,853,966 gallons were drawn from the Thames, and 85,533,036 gallons from the Lea and other sources.

Dr. E. Frankland, in the course of his report to the Registrar-General on the quality of the Metropolitan water supply last month, makes the following remarks:—"The Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained in every case a markedly increased proportion of organic matter as compared with the previous month's samples. This increase is due to the heavy rainfall and swollen state of the river, although the samples were collected prior to the severest floods which occurred at the latter end of the month. All the samples were clear and bright. The water principally derived from the River Lea, and supplied by the New River and East London Companies, exhibited no material alteration as regards organic matter; the proportion present in the New River Company's supply being but little in excess of that in the deep-well waters, whilst that in the East London Company's water was less than in any of the Thames supplies. Both samples were clear and bright. The deep-well water of the Kent and Colne Valley Companies and of the Tottenham Local Board of Health contained, as usual, only a very small proportion of organic matter; and the Colne Valley Company by softening their supply with lime thereby rendered it also of excellent quality for washing and all other domestic purposes."

POOLE GAS AND COKE COMPANY.—At the twenty-fifth half-yearly general meeting of this Company, held on Monday last week, the Directors, in their report, alluded to the death of the Secretary (Mr. John Budden), who had conducted the works, both practically and financially, to their satisfaction for so many years, and to the appointment of Mr. W. Davis as his successor, as well as Engineer of the works. The accounts presented showed a profit of £576. This allowed of the payment of dividends of 5 and 4 per cent. on the two classes of stock; which was agreed to. The Chairman (Mr. W. Pearce), in acknowledging a vote of thanks passed to himself and the Directors, said the Company had been most fortunate in securing the services of Mr. Davis, who had given the greatest satisfaction to all since he had been Manager. He added that during the seven years he had been Chairman, the Company had reduced the price of gas from 5s. 11d. to 4s. per 1000 to private consumers. They hoped with increased consumption and good management to return to the maximum dividend.

THE WAKEFIELD WATER-WORKS ARBITRATIONS.

The arbitrations between the Wakefield Corporation and the Wakefield Union Rural Sanitary Authority and the Local Board of Sandal Magna occupied the attention of the Arbitrator (Mr. E. Cousins, C.E.) at the Surveyors' Institution for three days last week.

Mr. Balfour Browne, Q.C., and Mr. J. Beverley appeared for the Corporation; Mr. Cripps and Mr. C. M. Atkinson for the Wakefield Union; and Mr. Mattinson, M.P., for the Local Board of Sandal Magna. The case, shortly stated, so far as regards the Wakefield Union, is that they gave notice to the Corporation of their intention to purchase the pipes and apparatus within their district, under the provisions of section 61 of the Wakefield Water-Works Act of 1880. The arbitration was for the purpose of assessing the price which they are to pay, and the terms and conditions of the transfer. The offer made by the Wakefield Union was upwards of £1100; but the sum required by the Corporation for the same thing was £52,000—the difference between them turning on the construction of the Act. The contention of the Wakefield Union was that they ought to pay only the value of the pipes and apparatus *in situ*; whereas for the Corporation it was argued that they must pay not only for the pipes and laying them, but also for them as a portion of the undertaking. In other words, the Union would take away a certain amount of revenue from the Corporation; and they must have the capital to compensate them. The case for the Corporation having been concluded, Mr. G. W. Stevenson, C.E., gave evidence for the Wakefield Union. He said that he had had large experience in advising corporations and water companies as to transfers of the latter undertakings. He had valued at £1127 the pipes, fittings, and other apparatus connected with the distribution of water belonging to the Corporation laid in the district of the Wakefield Union. He would not allow anything for compulsory purchase or prospective value, because the Wakefield Union simply exercised their option to purchase. Mr. Anthony Barr, of Liverpool, gave corroborative evidence. Mr. Cripps then summed up for the Wakefield Union, and contended that as the value of the property to his clients was only £1200, it was absurd to have to pay £52,000 for it. These figures were based on the assumption that the Wakefield Union would cease to take the water from the Corporation; but they were willing to enter into an agreement to be customers of the Corporation. Mr. Balfour Browne replied upon the whole case, arguing that the Corporation were entitled to the prospective revenue of the undertaking they were selling; and this amounted to £52,000, and not the £1127 for the pipes, as if the Corporation had nothing but old iron to sell.

The case between the Wakefield Corporation and the Sandal Magna Local Board was next gone into. Mr. Balfour Browne, Q.C., and Mr. Beverley appeared for the Corporation; and Mr. Mattinson, M.P., for the Board. The Corporation by their witnesses put the value, on the same basis as in the last case, at £39,000. Sir F. Bramwell, Mr. Rofe, C.E., and Mr. Coxon, borough accountant, were called for the Corporation. On behalf of the Local Board the offer made was £1010; and their case was supported by Mr. H. Mason, Solicitor to the Board; Mr. B. Shaw, of Doncaster, and Mr. A. Davey, of Sheffield. Mr. Mattinson, M.P., and Mr. Balfour Browne, Q.C., having been heard for their respective clients, the arbitrations concluded, and the Arbitrator will make his award in due course.

THE WALSALL CORPORATION AND THE SOUTH STAFFORDSHIRE WATER BILL.

At the Meeting of the Walsall Town Council on Monday last week, a report was presented by the Sub-Committee appointed to take charge of the opposition to the South Staffordshire Water Company's Bill, which, it may be remembered, after passing the Committee of the House of Lords, was withdrawn in the Commons. It set forth that the measure proposed to repeal certain provisions in the Company's existing Acts which had from time to time been inserted therein for the benefit and protection of the Corporation—such as, for instance, the clauses as to the breaking up and restoring of streets, the protection of gas-mains, and the enforcement of a constant supply of water under pressure sufficient to reach the top storey of every house in the borough; and also to substitute for the charges authorized by the existing Acts a scale of charges based upon "annual value," the mode of arriving at annual value being of a novel character, and at variance with a decision of the House of Lords, in which it was decided that "annual value" did not mean "annual rent," but the annual value to the owner after making necessary deductions for rates, taxes, repairs, &c. The report stated that if effect had been given to the Company's proposal, there would have been a hard-and-fast line fixed for the deductions, although the local rates actually paid by some of the places within the Company's limits vary from 2s. 1d. to 7s. 2d. in the pound; and this would have been manifestly unfair to consumers in the heavily-rated towns. The proposed scale also provided that the Company should not be required to supply any house at a less charge than 2s. 2d. per quarter, whereas under the Company's existing scale they were limited, as respected a large number of houses, to a much lower rate. Before embarking upon what was known to be a costly opposition, endeavours were made to come to an arrangement with the Company; but these endeavours failed. The Committee felt that, as they were forced into a contest in defence of the water consumers of the borough, it was an opportune time to seek certain amendments in the Company's Acts, so as to secure a limit to the Company's charge for water for trade purposes, a reduced scale for water used for sanitary and other public purposes, and a modification of the scale in respect of water supplied to dwelling-houses partly used as retail shops; to confer upon consumers the right to supply their own meters; and, in case Parliament decided to increase the scale of charges, to compel the Company to sell the portion of the undertaking lying within the borough, at a price to be settled by arbitration. The Sub-Committee considered that the effect of the Company's original proposal would have been to cast upon the water consumers in the borough an increased annual payment (over and above what it was contended, they were authorized to require if rateable value were taken as the basis of their charges) estimated at about £1000, which, if capitalized at $\frac{3}{4}$ per cent., would represent no less a sum than £30,000. It would thus be seen that the question of increased price was a very serious one, apart from the other objects of the opposition. As the result of the opposition before the House of Lords Committee, modifications were made in the Bill which reduced the estimated loss to the consumers in the borough to about £450 per annum, according to the Company's own figures; and in consequence of the strenuous opposition raised in the House of Commons, and the facts brought out there, the Committee refused to allow any increase in the Company's scale of charges. As this was the main object of the measure, the Company withdrew the Bill. The report was adopted.

BURSTING OF A RESERVOIR AT VALPARAISO.—According to a Reuter's telegram from Valparaiso, dated the 11th inst., nearly 100 houses have been laid in ruins, and several hundred persons drowned, in consequence of the bursting of a large reservoir, owing to heavy rains.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The Edinburgh and Leith Gas Commissioners have, I would remark, exercised a very wise discretion indeed in the appointment of Mr. Gibb, of the Edinburgh and Leith Company's office, to the post of Treasurer to the Commissioners, and Mr. Cockburn, of the Edinburgh Company, to the post of Collector. Where capacity is admitted, seniority should always have a prior claim; and it is gratifying to everyone to find the Commissioners recognizing this principle, and giving these important positions to the gentlemen to whom I think everyone will admit they naturally belong. Both of the gentlemen are exceedingly well fitted for the posts to which they have been appointed; and I can safely predict that, so far as their departments are concerned, the Commissioners will have little trouble in carrying on their business.

Both the Edinburgh and the Leith gas stocks may be regarded as having reached high-water mark, and began to recede. The heavy distribution of the Companies' assets, which has yet to take place, may keep the stocks at a high figure for some time; but after that they may be expected to go down to the level at which the investing public estimate the credit of the city of Edinburgh. At present about £290 is paid for the privilege of drawing £10 a year, which is clearly not a sufficient return for the outlay; but the person who is able to acquire a share will, at the distribution, receive from the Companies about £50. Nearly the whole of this sum may be deducted from the present price to find the probable future return, which will, in all likelihood, be a little under 4 per cent. During the past ten days the 10 per cent. stocks receded from £299 to £292, but rose again to £296. The 9½ per cent. stock fell from £280 to £275, at which it has remained for more than a week.

The Arbroath Gas Commissioners, at their meeting on Monday, overcame, but only by a very narrow majority, an opposition which does not rise in estimation the more it is studied, and resolved to go on with the extension and alteration of their works, as recommended by Mr. R. Mitchell, of Edinburgh. The opposition seem to belong to the class—unhappily too common in public life—who build too much upon the notion that "sufficient unto the day is the evil thereof." They seem content to go on with the works in their present unsatisfactory state, until events arise which will require something compulsory to be done, instead of taking the wise course of foreseeing and providing for eventualities. The Perth Gas Commissioners experienced something of the same sort last year, when some of their number saw the time fast approaching when it would be necessary to make provision for a largely increased output of gas. They succeeded; and, in the meantime, so have their brother Commissioners at Arbroath, although, it is true, one of the minority has threatened to re-open the question.

At the annual meeting of the Cullen Gas Company on Thursday of last week, a circumstance occurred which I never recollect having seen before—the setting aside of the Directors' recommendation, and the paying of a higher dividend. The Directors proposed a dividend of 5 per cent.; but the shareholders, taking the matter into their own hands, fixed it at 7½ per cent.

If the story told by the *Scottish Leader* on Monday last has any foundation in fact, the treatment of the inhabitants of Dalkeith by the Duke of Buccleuch has not been by any means magnanimous. His Grace's policies adjoin the town; and, according to the paper named above, for about 60 years it was supplied with water from an artesian well within his grounds. The water was pumped up to the town by a water-wheel; but a fire, about two years ago, destroyed the building in which the pumping apparatus was situated, and it has never been restored. The Duke's Chamberlain is accused of having sought to place too binding restrictions on the Commissioners of Police, which could not be accepted; and the result is said to be that thousands of gallons of excellent water were allowed to run to waste at a time when the inhabitants "were on short supply, or had to pay a high price to the Edinburgh authorities for what they required." The Commissioners, it is said, proceeded to bore for water on ground belonging to themselves; and finding an abundant supply, were about to utilize it, when the Chamberlain interposed, and intimated that, as the pipes of the old supply, which passed through his Grace's ground, were to be used, interdict would be taken out against the Commissioners. The outcome of all is said to be that the Commissioners have been put to the expense of laying a new line of mains, and adopting a route along the public road. The inhabitants are now enjoying a most abundant supply of excellent water. The last-mentioned circumstance is of most importance; and if the Duke was a little stiff in his terms, he has apparently gained nothing by being so.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

At a meeting of the Greenock Corporation Gas Committee held yesterday, there was a difference of opinion as to whether they should recommend to the Police Board a reduction of 2½d. or 5d. per 1000 cubic feet off the price of the gas for the year 1888-9. Some of the members were disposed to be more cautious than others; their belief being that 2½d. reduction would be sufficient in the meantime, and that it would at any rate obviate the necessity for any increase being made in the general taxation of the ratepayers by the Police Board. On the other hand, the advocates of the greater reduction argued that year after year the rate of 3s. 9d. per 1000 feet has resulted in a substantial balance to the good, which has been handed to the Board for the purpose of reducing taxation. At this there has of late been a considerable amount of grumbling, as the gas consumers naturally object to paying a portion of the taxes of the non-consumers.

Referring to the prospective reduction in the price of gas both in Greenock and Glasgow, an Ayr newspaper draws attention to the position occupied by that town in relation to the price of gas charged by the local Gas Company. The writer does not consider that his town is worse situated, so far as the supply of coal goes, than either Glasgow or Greenock, yet the price there remains at the same high level; and there is not, he says, any appearance or expectation of any reduction. He further remarks: "Nor is it easy to see that under the present Company we shall ever be much better; and as the community are wisely opposed to the taking over of the gas-works, we suppose we shall have to carry the old man of the sea on our backs until electricity takes the place of gas lighting." If I mistake not, the price of gas in Ayr is 4s. 7d. per 1000 cubic feet, which must certainly be regarded as a somewhat abnormally high rate.

At the last meeting of the Airdrie Town Council, the Convener of the Fire and Lighting Committee (Mr. Rankin) suggested that the street lamps of the burgh should be lighted continuously for the usual lighting period of eight months of the year, including moonlight nights, at the same rate as 7s. for six months' lighting, after deducting sixty days from the eight months for supposed moonlight nights; the total extra cost being estimated at only about £32 15s. If the Council would agree to his suggestion, he anticipated that the Gas Company would light the lamps at 9s. 4d.

each all the year round, in place of 7s. for eight months; the total extra cost being only £32 15s. The Provost remarked that there was no doubt that they sorely needed light on some of the moonlight nights. Mr. Adam was also of opinion that the lamps should be lighted all the year round, as in the neighbouring burgh of Coatbridge. The suggestion was unanimously approved; and it was remitted to the Fire and Lighting Committee to make the necessary arrangements with the Gas Company.

At the meeting of the Mid and East Calder Gas Company yesterday week, Mr. S. Hislop was unanimously appointed Secretary, in room of his late father, who had faithfully discharged the duties of this post ever since the Company's formation. The meeting agreed to record in the minutes an expression of the great loss sustained in the death of a gentleman who had been one of the originators of the Company, and had always taken a lively interest in its affairs.

It is confidently expected that the Greenock Water Trust will, at their next meeting, agree to reduce the domestic water-rate from 10½d. to 9d. per pound of rental; being the amount by which it was increased a year ago, when the financial condition of the town looked much more satisfactory than it is now.

The Gourrock Burgh Commissioners have recently agreed upon carrying out an important scheme for the extension of the water supply of the town, which, it is said, will render it capable of meeting the wants of a population of 25,000. The water is to be brought from Loch Thom, which is part of the Greenock supply works. It is very pure, and can be supplied to houses on a much higher level than any that have yet been built. The Commissioners have agreed to borrow £2500 to pay for the works rendered necessary by going to a fresh source of supply. When the Gourrock Extension Railway is opened for passenger traffic, the new demands will probably exhaust all the present power of supply; and in the course of about ten years, it is thought that, with ordinary prudence in the management of the water-works, the assessment for water purposes may be reduced to 2d. per pound of rental.

Up till yesterday the week's pig iron warrant market was strong, and prices went up at a somewhat bounding rate. On Wednesday and Thursday Scotch iron touched 40s. cash per ton; being an advance of 7d. from the price yesterday week.

Matters continue favourable in the local coal trade. Sellers are now able to get orders more freely at the advancing quotations—in some cases 1d. and 2d. per ton higher for shipping sorts. It is just possible that the wages question will soon show itself both in Lanarkshire and in Ayrshire.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Aug. 18.

Sulphate of Ammonia.—The market has continued dull during the whole of this week; nevertheless the possibilities of an improvement still exist. Buyers are more or less on the alert; and it does not follow that they can by their cautious movements always control the market, even by a concerted action, which is not the case at present, nor likely to be. The principal enquiry, however, is for the end of the present and the beginning of next year; and it is, to say the least, a favourable symptom that the limits are based on to-day's values. But these producers do not think of accepting; preferring to take their chance about the future—the tendency of the nitrate market buoying them in their hopes of better prices by-and-by. In consequence of the present position, the transactions are very small; and the unseasonable weather contributes no little to the present inactivity. To-day's quotations are £11 7s. 6d., Hull and Liverpool; and £11 6s. 3d., Leith.

LONDON, Aug. 18.

Tar Products.—The feature of the week has been an active demand for anthracene, which, owing to its scarcity, is difficult to procure even at advanced prices. Other products are flat. Stocks are low; and distillers are therefore not affected by the operations of dealers. Prices may be taken as follows: Tar, 17s. 6d. to 21s. per ton. Benzol, 90 per cent., 2s. 10d. per gallon; 50 per cent., 2s. 4½d. per gallon. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate is distinctly dull; and notwithstanding that considerable shipments have been made during the week, new orders are undoubtedly scarce, although prices quoted do not show a fall on last week. Prices: Sulphate of ammonia, £11 5s. to £11 7s. 6d. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Aug. 18.]

Sulphate of Ammonia.—This market still continues dull for prompt delivery; but as there is so little offering, prices have not seriously receded—£11 7s. 6d. being the figure offered by speculators by whom all the present business is being done. Although the price f.o.b. Leith has followed the slight decline, at other ports there has been a fair business doing, and the shipments have been well maintained. Beckton quotes at £11 12s. 6d.; while business has been done in London outside makes at £11 13s. 9d. Hull value is £11 7s. 6d.; and Leith and Liverpool may be fairly stated to be £11 5s. The Sulphate of Ammonia Association is doing good work in disseminating information relating to the price and shipments from the various ports; and we understand the Council is busy preparing a new edition of the "Handbook" on the employment of sulphate for the use of farmers, agriculturists, and market-gardeners.

Tar Products.—Benzoles still retain their old price; and 2s. 4d. for 90/90's has, we understand, been paid during the past few days. As for 50's the price remains unchanged; and 2s. 8d. is mentioned as its extreme value. There is a good demand for solvent naphtha at old rates. Creosote is moving off well; and the better quality, known as Lucigen oil, is being largely shipped to the Spanish mines. Crude carbolic is easier; and we have heard of as little as 7d. per gallon being accepted for crude disinfecting cresylic. Anthracene is very firm. Sales have been made of "B" quality, at 1s. 2d.; while 1s. 6d. is being asked for "A." Pitch may be quoted at 13s. to 13s. 6d. at port of shipment. Distillers seem holding for an advance, as inquiry for parcels generally leads to the reply that they have none to sell.

EXTENSION OF THE BRENTWOOD GAS-WORKS.—Owing to a contract having been entered into by the Brentwood Gas Company to supply a large additional quantity of gas to the new County Asylum, as well as to the increase of their business generally, the Directors are about to considerably enlarge their works, in order to meet the requirements of this extra consumption. The new works have been designed and will be carried out under the direction of Mr. Jabez Church, M. Inst. C.E., of Westminster. It may be mentioned, as an indication of increased business in gas and water supply in Essex, that at the present time Mr. Church is engaged in enlarging, reconstructing, or altering no fewer than six gas and water works in the county.

BRIGHTON AND HOVE GENERAL GAS COMPANY.—The half-yearly meeting of this Company is to be held on the 7th prox., when the Directors will submit their usual report on the working of the undertaking. They state that it is their intention to reduce the price of gas 2d. per 1000 cubic feet on and after Jan. 1, 1889. They announce, with much regret, the death, on July 27 last, of Mr. J. O. N. Rutter, who was for nearly 50 years the highly-esteemed Engineer and General Manager of the Brighton Gas Company, whose honourable and useful career has ended at an advanced age. The following dividends are recommended:—At the rate of 10½ per cent. per annum on the original shares; 7½ per cent. per annum on the "A" shares; and 6 per cent. per annum on the "B" preference shares. The amount available for these dividends is £32,142 18s. 4d.

WEYMOUTH CONSUMERS' GAS COMPANY.—The half-yearly general meeting of this Company was held last Thursday, under the presidency of Mr. R. Damon. The Directors in their report recommended the declaration of dividends at the rates of 10 and 7 per cent. per annum on the two classes of stock. The Chairman, in moving the adoption of the report, said that, notwithstanding the reduction in price, there had only been a very small increase in the quantity of gas supplied in the six months ending in June last, as compared with the corresponding period of 1887. He quoted from a memorandum prepared by the Secretary and Manager (Mr. James Lowe), to the effect that there had been a decrease in the gas-rental to the extent of £322; tar had slightly increased in price, and £37 more had been received for it; and the returns for sulphate had been better, to a similar amount. The report was adopted. Thanks were accorded to the Chairman and Directors, as well as to Mr. Lowe, who was congratulated on his restoration to health.

CORK GAS CONSUMERS' COMPANY.—The annual meeting of this Company was held last Tuesday—Mr. T. Mahoney presiding. The Directors' report, recommending a dividend at the rate of 8 per cent., was alluded to in the *JOURNAL* last week. In proposing the adoption of the report, the Chairman pointed out the increase in the freights, and said there would probably be a still greater increase. This, he remarked, was a good sign of the revival of trade. He next referred to the question of electric lighting, which he said had been frequently discussed by the Directors. While admitting that in London there might be an opening for electric lighting, elsewhere it could not compete with gas on account of the cost of production. Mr. Denny Lane, their Secretary, had told them, at the height of the Edison fever, that he never met an electric invention of Edison's that he had not been familiar with for years. This view had been confirmed by others. The Chairman warned the shareholders not to part with their shares under any apprehension of the introduction of electric light. The report and statement of accounts were adopted.

* Station closed during alterations.

SULPHURETTED HYDROGEN.—None on any occasion.

PRESSURE.—In excess on all occasions.

Note.—The standard illuminating power for common gas in the Metropolis is 16 sperm candles, and for cannel gas 20 sperm candles. Sulphur not to exceed 17 grains in 100 cubic feet of gas; ammonia not to exceed 4 grains in 100 cubic feet of gas. Pressure between sunset and midnight to be equal to a column of 1 inch of water; between midnight and sunset, 6-10ths of an inch.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—GWYNNE & CO.,

ADDRESS FOR TELEGRAMS: "GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS &c., &c.

Catalogues and Testimonials on application at the above address.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

OXIDE OF IRON.

THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 350,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 161 to 163, Palmerston Buildings, Old Broad Street, LONDON, E.C.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, 158, Palmerston Buildings, Old Broad Street, LONDON, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH.

Gas Engineers, supply all the most approved SCOTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 80, ST. ANDREW SQUARE, EDINBURGH, } Scotland.
No. 54, BERNARD STREET, LEITH, }

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE & CO, 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56, MILLBANK STREET, LONDON, S.W.

[Telegraphic Address: "PRECISION LONDON,"]

Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c.

* See Advertisement on Page III. of the Wrapper of last week's issue.

W. C. HOLMES & Co., Huddersfield, AND 80, CANNON STREET, LONDON,

Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings.

* See Advertisement p. 354 of this week's issue.

Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

TUBES.

FOR Gas, Steam, and Water; Galvanized White Enamelled, and Hydraulic Tubes and Coils JOHN SPENCER, Globe Tube Works, WEDNESBURY and 14, Great St. Thomas Apostle, LONDON.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour.

Highest References and all particulars supplied on application.

SULPHURIC ACID.

HUGH WALLACE & CO., Chemical Manufacturers (the old-established firm), supply the above, which is specially adapted for making White Sulphate of Ammonia. The latter purchased in any quantities at highest market prices, or contracts for the year.

For price and terms apply Botoiph House, Eastcheap, LONDON, E.C.

TITLE AND INDEX TO VOL. LI.

In consequence of several inquiries as to the above, we call our readers' attention to the paragraph which appeared in our issue for the 24th ult., (p. 157), and remind them that a Title-page and Index to Vol. LI. of the JOURNAL—January to June, 1888—have been prepared, and will be forwarded by the Publisher post free on receipt of a post-card.

TO ADVERTISERS.

ADVERTISEMENTS for the next number of the JOURNAL must be received by Monday, 12 o'clock noon, to ensure insertion; but as the Advertisement sheet of the JOURNAL is sent to Press the first thing on Monday Morning, Advertisers will please bear in mind that Orders for Alterations in or Stoppages of PERMANENT Advertisements should be received Not Later than Two o'clock on SATURDAYS.

Telegraphic Address: "GASKING LONDON."

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, AUGUST 28, 1888.

THE LOCAL GOVERNMENT ACT.

WE have so often referred to the progress through the House of Commons of the Local Government (England and Wales) Bill, that now the measure has passed it is right [that we should devote some attention to this great piece of legislation as a whole, with special reference to those portions of it which particularly affect the interest with which the JOURNAL is most closely identified. We begin, therefore, by recommending every one of our readers resident in those parts of the kingdom affected by the measure to procure a copy of the Act, and to study it carefully, with a view to understanding

the magnitude of the change that is to come over the internal administrative organization of the country as from the beginning of next year. This is not precisely a holiday task; but the trouble will be well repaid. Parliament has done nothing like this for very many sessions. It is a solid, serious piece of constructive legislation, with only the slightest bearing upon party politics, and with nothing in it to form an election cry, or to catch votes by pandering to unwholesome party appetites. Whether it will work well or ill cannot, of course, now be known. It is quite possible that, as soon as it is put into operation, flaws of drafting or definition may be detected of more importance than much that has aroused the fiercest controversy in the House; but it is idle to waste time in anticipations of such evils, which will be vexatious enough when they come. Lawyers will soon rush to the front with books explanatory of the Act; but it will be best to study the measure itself. Although it forms, as published, a substantial bulk of printed matter, it is not more voluminous than many a Corporation Act, and does not look so portentous as did the Orders containing the multitudinous amendments proposed while it was in Committee. It is divided into six parts, containing altogether 126 clauses, and three schedules. The first part constitutes the County Councils, the establishment of which is the great feature of the Act. These Councils will consist of the Chairman, Aldermen, and Councillors; and to them will be entrusted the administrative and financial business of their county, as defined by the terms of the Act, precisely as in the case of a borough divided into wards. The county councillors are to be elected, one only for each electoral division, for three years, and will consequently all retire together. The Chairman is to hold office for one year, during which time he will be a Justice of the Peace. Such is the composition of the last new popular governing body, the constitution of which it is to be supposed is the fruit of experience gained in connection with all other elective local authorities.

Gas companies will be in touch with these new bodies at a number of points. First, and of great importance, is the matter of assessment. It is to be hoped that this part of the work of the County Councils will be done properly. The execution of the Acts relating to weights and measures, including gas-meters, will be part of the duties devolving upon the County Councils, as will the registration of rules of scientific societies. All main roads will also be placed under their control; so that gas undertakings will be delivered from the multiplicity of highway authorities by which they are occasionally plagued. But every authority having power to light the roads in their district will have the same power and duty to light any main road in their own area. The Rivers Pollution Prevention Act, 1876, will also be administered by the County Councils; so that a necessary piece of sanitation that has hitherto suffered from being nobody's business will at last come into hands strong enough to carry its provisions into effect, and manufacturers will be treated with greater uniformity than hitherto. An important proviso is that County Councils are to have power to oppose Bills in Parliament, and are relieved from the obligation to obtain the consent of owners and occupiers for this purpose; but they will not be able in like manner to promote Bills. Boroughs named in the schedule which on June 1 last had a population of not less than 50,000, or were counties in themselves, are to enjoy the position and privileges of being separate counties named "County Boroughs" in the Act. On the other hand, the local authorities in boroughs of less than 10,000 inhabitants are to be merged in the new governing authorities for the counties in which they are situated. A writer in *The Times* hails this extinction of the small borough authorities as a blessing, for the reason, among others, that these places are often hotbeds of corruption and jobbery. This is a severe, and, as it appears to us, an uncalled-for commentary upon bodies which, on the whole, have done fairly well; and especially, in respect of jobbery, the size of boroughs is not always a protection to the ratepayers.

The most striking of all the changes wrought by the Act is in connection with the government of London. After all the fruitless talk about the reform of the municipal arrangements of the Metropolis, it is very remarkable that, almost as an incident of this large measure, London is to be endowed with more administrative autonomy than it has ever enjoyed before. The County of London will be constituted of the huge "province covered with houses" now known as forming parts of Middlesex, Surrey, and Kent; with its own Sheriff, Court of Quarter Sessions, and Commission of the

Peace, and all the unity of administration that this separation implies. The number of county councillors for London will be just double the number of members of Parliament authorized for the different boroughs of the Metropolitan area; with one-sixth of the number of county aldermen. All the powers, duties, and liabilities of the Metropolitan Board of Works—but not, it is to be hoped, the bad name of this body—are to be transferred to the new authority, who are declared the lawful successors of the old organization. Thus the County Council for London will start fully equipped with a heavy load of work and responsibility. A noteworthy point in the new order of things is the absence of any provision for the payment of the Chairman of the Council. The present Chairman of the Metropolitan Board of Works has £2000 a year for his trouble; but his successor will have more to do for nothing, although he may have a paid deputy. With regard to roads in the County of London, these may remain under the care of the Vestries, acting as District Councils under the Act. The new Court of Quarter Sessions for London may have a Stipendiary Chairman, or Deputy-Chairman, who will be empowered to sit alone. There is nothing authorizing the London County Council to meddle in any way with the supply of gas, except to test it; and the powers of the Board of Trade in connection with the Gas and Water Works Facilities Act are not specifically transferred to the new authorities. It is well understood, however, that this may come in time, when the new machinery has got into proper working order. There is a provision in the Act whereby a Secretary of State may transfer at any time a portion of his present duties to a County Council; so that if these organizations should command public confidence, the process of decentralization may be carried out to a considerable extent without necessitating a fresh Act of Parliament for the purpose.

In this review we have not been able to do more than summarize, in the briefest possible fashion, the leading provisions of one of the most important reforms of the present reign in regard to local self-government. One can hardly yet realize how great a change is to come over the nature of county administration with the beginning of another year; but the announcement that there will be creations of county stocks, just as there are now borough stocks, will perhaps help more than any other statement to indicate how thorough and far-reaching the change will be. It, of course, remains to be seen whether the fullest possible benefit is to be derived in practice from the alterations in county government enacted by the Legislature. Some people are sanguine enough to believe that London, for instance, will almost immediately quicken into independent, conscious political life as a whole; and that the carelessness and apathy of its population as regards everything relating to the men who spend the rates, and the objects for which the money is spent, which has always been such a hopeless obstacle to truly responsible local government for this huge Metropolis, will disappear like darkness before the dawn. We doubt it. London is too big, its people are too divided by sheer latitude and longitude, for there to be anything of that close knowledge of the real characters of its public men which in smaller aggregations of humanity constitutes such a precious safeguard for the proper working of an electoral system. Nobody knew who were the true men and who the self-seekers on the Metropolitan Board of Works, before the Royal Commission brought the doings of this moribund body into unwonted publicity. No local governing body in any other part of England could have gone on so long, without the public generally knowing something about the characters of the members, as the Metropolitan Board of Works has done in London, with all its newspapers. There is little prospect of a really effectual change in this respect; but we must hope for the best. With regard to the rest of the country, it is but justice to the magistrates as a body to bear testimony (before they are relieved of even so much of their duties as will shortly be transferred to their elective successors) to the public spirit, efficiency, and respect for economy which they have displayed in their administrative work. It is to be feared that the new authorities, having the feeling that they are dealing with their own moneys, may be more lavish in expenditure than their predecessors, and may in this respect be induced to follow the bad example set by many reformed Municipalities when city and borough stocks were as great novelties as county stocks will be for a few years to come. Many homilies have been preached in advance upon this topic, however; and so we will say no more about it, but conclude this notice of the Local

Government Act with the expression of a hope that it may be found in actual working to justify the trouble that the Administration and Parliament have taken concerning it.

THE AFFAIRS OF THE LIVERPOOL UNITED GAS COMPANY.
The Liverpool United Gas Company have just held their annual general meeting; and, as will be seen from the report of the proceedings in another column, the statement that the Chairman (Mr. E. Lawrence) had to make to the proprietors was of a very satisfactory character. We do not use this somewhat hackneyed expression merely with reference to the balance-sheet of the Company, although this fully merits the description; but rather with regard to something that follows from these figures. It was pointed out by the Chairman that, whereas a twelvemonth ago (owing, as he said, to the bad state of trade in the city and district) the consumption of gas was restricted, and the Company did not earn their full dividends upon the year's working, this year circumstances have materially changed for the better, and the improvement in the trade of Liverpool is reflected in the condition of the Company's revenue account. Such a reflection cannot but be gratifying to the good citizens of Liverpool who happen to be fortunate enough to hold stock in the Gas Company; for if anything is capable of adding to the satisfaction with which an honest man regards a profitable investment, it is the thought that his own prosperity is the consequence of well-doing on the part of his neighbours and those with whom he does business. The Directors are not exempt from the common lot of their kind upon similar occasions; and the chorus of congratulation which they may have expected to follow upon the Chairman's statement was broken by a single voice of hostile criticism, lifted up by a gentleman who seemed to think that the gas undertaking of the Wallasey Local Board, with which he avowed his own connection, was much better managed than that of the Company, especially in the matter of their coal supplies. It is remarkable how much local criticism finds to feed upon in the coal contracts of the Liverpool United Gas Company, the disposal of which is never satisfactory to everybody happening to be either directly or indirectly interested in such matters. As the Chairman pointed out, however, the manufacture of gas by a Company under the supervision, as regards illuminating power and purity, of a City Corporation, is a very different matter from the supply of nominally the same commodity by a Local Authority for their own profit. The occasional cropping up of these continual topics at Gas Companies' meetings does no harm; and when the points raised can be disposed of so quickly and satisfactorily as was done by the Chairman of the Liverpool Company, the attraction of the meetings for shareholders of an inquiring mind is materially enhanced, without leaving any unpleasant savour behind.

THE LANCASTER CORPORATION AND THEIR GAS MANAGER.

In another column will be found the report of Mr. C. Armitage, the Gas Engineer to the Corporation of Lancaster, upon the working of the undertaking in his charge during the past twelve months; and a very good showing it is. There is some pleasure in looking at a statement of this character. In making 20-candle gas at a net cost of only 11·68d. per 1000 cubic feet, with a leakage account of but 3·29 per cent., Mr. Armitage has certainly done admirably for his employers. In the course of the debate in the Town Council upon the report and accounts of the Gas Department, Alderman Hatch, after complimenting Mr. Armitage upon his work, took credit to the Gas Committee for their treatment of their Manager. He said: "They paid him a fair salary, and they did not interfere with him continually in suggesting this and suggesting the other thing in matters they knew very little about." It is most gratifying to find such a state of things existing in relation to the gas supply of Lancaster as is depicted in these words, after all that one has heard of late respecting the treatment of Gas Managers by some Corporations. Of course, we cannot deny that the aphorism that good servants make good masters applies in this case; but also, on the other hand, it may be cited in order to show that good masters make good servants. If the Lancaster Corporation have a good officer in Mr. Armitage, they certainly know how to treat him, if, as Alderman Hatch remarked, they pay him well and leave him alone in matters of detail. We are no advocates of the principle of making the Gas Manager the master instead of the servant of his employers. He has a place, and he should be kept in it; and it is, moreover, a great relief for the Manager when he knows he can rely upon

his Committee to take that responsibility in matters of policy which rightly belong to them. The Manager can no more assume the proper functions of his Committee than can the Committee usurp those of the Manager. Examples of the latter blunder are, however, much more frequent than of the former. All this requires to be taken to heart by those whom it may concern. For the present, we have only to congratulate Lancaster upon the possession of Mr. Armitage, and Mr. Armitage upon finding a sphere where not only is there room for his abilities, but where also these are appreciated. We have no wish to exalt Mr. Armitage as though he were a *rara avis in terris*. There are good Gas Managers outside Lancaster; but in Lancaster there is evidently an example of the right man in the right place, which makes it pleasant to contemplate.

REMARKABLE NEWS FROM SWANSEA.

STRANGE intelligence reaches us from Swansea, where the relations between the Corporation and the Gas Company have lately been somewhat strained, in consequence of the Company having applied for a Provisional Order, which was strenuously opposed by the Corporation with only moderate success. The Company have been compelled to raise the illuminating power of their gas beyond the point at which they can produce it from Welsh coal—a peculiar result of the public-spirited action of the Town Council to diminish the amount of money which the Company must spend locally for their supplies! In view of the fact that they did not earn their dividend last year, when selling a less expensive article, the Directors of the Company have been compelled—much against their will, as we must believe—to raise the price of gas by 4d. per 1000 cubic feet, which has, of course, brought them into great disgrace with the Town Council, who are talking about adopting electric lighting and all sorts of retaliatory measures. The most remarkable thing in connection with this condition of affairs in the borough of Swansea is, however, that some benefactor of his species (whose name is at present unknown) has put himself in communication with some of the members of the Town Council, and has offered to light the town for nothing, provided that the Corporation will adopt a particular lamp, the character of which has not transpired. That there might be no mistake about it, the member who brought the matter under the notice of the Town Council showed that any town containing more than 80,000 inhabitants might be similarly favoured; for this was the only condition insisted upon by the undisclosed philanthropist. Another member vouched for the lamps in question as being “extremely beautiful;” and it was remarked that, by adopting them, the town would save the £3770 a year paid for the public lighting. There is some mystery about these lamps; for in the letter in which they were offered to the Corporation of Swansea, it was stated that they would be provided and fixed, and kept clean and in working order, free of cost to the town, and the tenderer would also “pay the cost of water, should it be necessary to “use water.” What can this mean? Has the concealed philanthropist discovered a way of burning water in street lamps? And even so, how can he provide and maintain them for nothing? There is something mysterious about it all, which the Corporation of Swansea ought, in mercy to a bewildered public to clear up by promptly accepting the offer of the unknown; and in this, as there is nothing to pay, there can be no risk. Their duty to the ratepayers demands nothing less; for as the choice lies between the Gas Company, who require to be paid for their work, and a person who offers a supply of beautiful lamps—with water—for nothing, it can scarcely be doubtful on which side the choice of the thrifty Welshmen will incline.

PROPOSED GAS MANAGERS' ASSOCIATION FOR THE EASTERN COUNTIES.—Mr. H. Wimbhurst, the Manager of the Sleaford Gas-Works, has been inviting an expression of opinion by the managers of gas-works in the eastern counties, on the subject of a suggestion made by several members of The Gas Institute who have charge of works in that portion of England that a District Association should be formed for those counties. It is proposed to hold a preliminary meeting in some convenient town (Peterborough has been mentioned as most suitable) in the last week in September. Several gentlemen—including Mr. J. Carter, of Lincoln, and Mr. J. Barton, of Peterborough—have offered Mr. Wimbhurst their support; and the project only awaits favourable reception by the general body of East Anglian gas managers to be established on a working basis. Mr. Wimbhurst will be pleased to communicate with any manager who has not received a copy of the circular he has been sending out on this matter.

Water and Sanitary Affairs.

AN ambitious project for supplying Paris with water has been submitted to the Municipality of the French capital by M. Ritter, a Swiss Engineer. In this scheme the three Jura lakes of Neuchâtel, Bienne, and Murten, in connection with the new Hagneck Canal and the River Aar, are treated as three natural reservoirs; and the supply is to be drawn off from the lake of Neuchâtel by a heading about 260 feet below the surface of the water. The latter seems a somewhat extraordinary arrangement; but the most formidable part of the project is a tunnel 22 miles in length, to be formed under the Jura Mountains—an engineering achievement akin to that of the Channel Tunnel so ardently advocated by Sir Edward Watkin. From the lake of Neuchâtel to Paris the distance is 312 miles. It is computed that the work could be executed in six years, at a cost of £12,500,000. It will be interesting to compare this with some of the schemes for supplying London with water from a remote point. Mr. Bateman proposed to bring a supply of 230 million gallons per day from North Wales, the distance being 183 miles, and the estimated cost £11,400,000. Messrs. Hemans and Hassard devised a plan for supplying London with water from the lakes of Cumberland and Westmoreland; the quantity being 250 million gallons per day, and the distance 270 miles. The estimate for this undertaking was £13,500,000. It will be seen that the cost assigned for the Paris scheme comes midway between the estimates for the two London projects. Yet the distance to be traversed in the French scheme is 42 miles greater than that of the longest proposed for London. In amount, the estimate of M. Ritter falls nearly £2,000,000 behind the sum which has been expended on the Metropolitan Water-Works. But the capital of the London Water Companies has been spent in distributing as well as in collecting the water; and the population supplied is 5,482,000, compared with 2,261,000 in the French capital. As an engineering scheme, M. Ritter's proposal is highly creditable to his ingenuity. The financial feature is the difficulty, considering what this Jura tunnel is likely to cost, despite the clever appropriation of hydraulic power from contiguous rivers. Allowing that French land is cheaper than English, yet if Messrs. Hemans and Hassard considered £13,500,000 requisite to bring a supply from Ullswater along a route of 270 miles, we hardly see how M. Ritter will be able to pierce the base of the Jura range, and traverse 312 miles, for £1,000,000 less.

Yet more analyses! When will the chemists leave the river alone? Sir Henry Roscoe has suggested that there should be an exhaustive examination, physical and microscopical, of the condition of the foreshores of the Thames from Barking to the mouth of the river, including the whole of the estuary. We understand that this exploration is to extend along the coast to Clacton on the one hand, and Margate on the other. The Works Committee have approved the proposal, and the Metropolitan Board of Works have adopted it; so that it is to be done. The steamer *Bazalgette* is to be told off for the expedition, like another *Challenger* scouring the seas in search of scientific information. Sir Joseph Bazalgette is to send an assistant to examine and report from an engineering point of view; while Mr. Dibdin, with two assistants, is to carry out the chemical inquiry—the whole affair to be under the superintendence of Sir H. Roscoe. It is rather surprising to find that the work is to be done in a fortnight. If there are many samples to be taken, this period of time can scarcely include the completion of the analyses. The object of the exploration is to provide accurate data as to the present state of the foreshores, in anticipation of any complaints as to injury done by carrying the sewage sludge out to sea. If Southend or Clacton, Sheerness or Margate, venture to assert that they are assailed by floating sludge, the Metropolitan Board will fall back on chemistry, and produce the analyses. Yet it will not be the Board, but the County Council, that will have to look the matter in the face. Perhaps the new authority will upset everything, and have nothing to do with sending the sludge to sea. New brooms sweep clean; and Sir H. Roscoe's report on the forthcoming voyage of discovery may be coolly ignored. Sir Robert Rawlinson protests against the scheme of the Metropolitan Board in respect to the sewage; and in so doing makes a somewhat remarkable statement. He estimates the volume of the London sewage at 200 million gallons per day, after which he argues that the new works are to treat 90 million gallons, and asks, “What is to be done “with the 110 million gallons over and above?” This is to forget that the Barking works only deal with the sewage

belonging to the northern side of the river; while other works at Crossness take the sewage of the southern side. It would also be interesting to know where Sir Robert gets his estimate of 200 million gallons per day. It is always difficult to arrive at the true total of the London sewage, as that portion on the northern side which comes from the higher levels is not pumped, but flows on to the outfall by gravitation. But Sir J. Bazalgette reckons on an average of no more than 162,500,000 gallons of sewage per day when the population has risen to 5,200,000. In one instance, we find him taking a yet lower estimate for the sewage. Mr. Dibdin appears to reckon on 160,000,000 gallons. In a letter on the sewage question by Mr. E. Rider Cook—a leading member of the Metropolitan Board—we find it stated that “the returns made by the Engineer and Chemist show that the average daily flow of the sewage, from May to September, was practically 175,000,000 gallons.” The range is rather wide; and we should like to know which is nearest the mark. The population of London is under 4,800,000.

MASONIC.—In the list of candidates for the October election to the Royal Masonic Institution for Girls, we notice the name of Annie Winifred Belton, who is an orphan niece of Bro. William Belton, P.M. 117, P.G.O., Shropshire, Secretary and Manager to the Shrewsbury Gas Company. The case is, we believe, a very deserving one; and Mr. Belton asks us to mention it, in the hope that those of his brother gas officials who possess votes will, if possible, kindly aid him in securing the election. He will gladly afford any desired information, or forward cards detailing the case to anyone willing to assist.

AMERICAN GASLIGHT ASSOCIATION.—The Secretary of this Association (Mr. C. J. R. Humphreys) has issued to the members his usual announcement as to the arrangements for the forthcoming meeting, which is fixed to take place at Toronto on the 17th, 18th, and 19th of October. He states that, according to present indications, the gathering will be eminently successful. The following papers have already been promised:—“Experience in Distributing Gas under Extremely Low Temperatures,” by Mr. D. H. Geggie. “Observations during Many Years’ Experience in the Gas Business,” by Mr. James R. Smedberg. “Construction of Gas-holders with Wrought-Iron or Steel Tanks above Ground,” by Mr. F. Mayer. “The Steam Stoker and Improved Charger,” by Mr. A. Q. Ross. “Daily Experiences and Observations of a Gas Manager,” by Mr. James Somerville. “Coals for Gas Making,” by Mr. J. D. Perkins. A special feature of the meeting will be the offer of a prize of \$25 for the best paper on “Naphthalene.” This will be the first time the Association has met in Canada; and there is no doubt the proceedings will be interesting and profitable.

IRON AND STEEL INSTITUTE.—The autumn meeting of this Institute took place in Edinburgh last week (the proceedings opening on Tuesday), under the presidency of Mr. Daniel Adamson, of Manchester. The members received a hearty welcome from the Lord Provost (Sir T. Clark), as representing the Municipality, and the Principal of the University (Sir W. Muir), as representing the Senate. The business was transacted in the Examination Hall of the University. The reading and discussion of papers occupied the members till one o’clock, and after luncheon in the Library Hall, the rest of the day was devoted to an inspection of the celebrated Broxbourne Oil-Works, with alternative excursions to the Newbattle Collieries and the Leith Harbour and Docks. In the evening, at the invitation of the Lord Provost, Magistrates, and Council, the members of the Institute attended a *conversazione* in the Science and Art Museum. On Wednesday morning the business of the meeting was concluded; and the remainder of the day was spent in visiting the Forth Bridge. In the evening the annual dinner took place at the Waterloo Hotel. On Thursday the members visited the Glasgow Exhibition. The meeting, on the whole, was highly successful.

THE OHIO GAS SPRINGS.—American papers report the proceedings of Dr. Ernest Weisenbauer, Professor of Geology in the University of Heidelberg, who has gone to America to investigate the district of the natural gas springs at Findlay, in the State of Ohio. He is of opinion that the extent of these springs has been much underrated, and that, at a considerable depth below the township of Findlay, there is an immense cave filled with gas which might easily explode. The Professor made use of a shaft through which the gas rises to the surface in order to connect a very sensitive telephone apparatus with the solid strata lying beneath the gas receptacles, and he came to the conclusion that a more or less solid non-conducting mass, about a mile in thickness, is interposed between the huge gas cave and a glowing furnace. At first he could not credit what the indications pointed to; but a protracted investigation, carried on at various points within a radius of three miles, has convinced him of the fact. He believes that the heat of this subterranean furnace is 3500°. He considers that the average distance of the cave from the surface is about 1200 feet, and that it is even less beneath the town of Findlay. It is right to add that Professor Gilbert, of Washington, has expressed great doubt as to the correctness of the conclusions or observations of the Gorman geologist. Notwithstanding the above, the *Progressive Age* is of opinion that the supply of natural gas in America will be early exhausted.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 390.)

BUSINESS on the Stock Exchange during the past week was decidedly quiet; and taken altogether the markets have ruled flat. This was partly owing to the general want of activity; but it was also in a measure produced by Continental affairs—the Boulanger elections and the Crispi note. Money has been in good demand, and the market has shown increased activity; but the Bank rate remains unchanged, and there is no apparent probability of any alteration in the near future. Gas was extremely quiet at the beginning of the week, but rapidly became more brisk. It is very firm; and there is every reasonable prospect of a further advance in favour. The Metropolitan Companies especially have been in good request; the demand, indeed, exceeding the supply. The condition of the Metropolitan Electric Supply Company may have something to do with this. It will be remembered that less than a month ago this Company’s prospectus was issued with a tremendous flourish of trumpets. There was a good demand for the shares—whether a genuine or an artificially fomented demand we cannot now discuss—and Metropolitan gas stocks had a heavy fall. But a rapid change has come over. The electric shares are at a very large discount, if indeed they are saleable at all; while the old reliable illuminant stands as firm as ever. This is not encouraging for the gas “bears” in the future; and we shall not expect to see another electric lighting prospectus for some time to come. As the result of the week, all three of the Metropolitan Gas Companies have advanced. Brighton and Hove has also improved, thanks to its prosperous past half year. Foreign undertakings have been steady, without any alteration but a rise in Buenos Ayres debentures. There has been rather more activity in Water; and the same slow and progressive rate of advance in quotations which has characterized the last two months is still in action. Lambeth is the chief gainer; and Chelsea and Southwark and Vauxhall are also slightly higher.

The daily operations were: On Monday a single transaction in Monte Video was all the business marked in Gas; and two transactions in Water were the sum total. Tuesday was more active, but business was still much below the average. Commercial new rose 1; Gaslight “A,” 2; and South Metropolitan “B,” 3. In Water, Chelsea advanced 1. Wednesday’s Gas business was light; not one of the big issues being touched at all. Buenos Ayres debentures improved 1. Water was firm and unchanged. Gas was more active on Thursday. Brighton and Hove advanced 1. Water was noticeable for the firmness of Lambeth; the 7½ per cents. improving 4, and the debenture, 1½. Friday’s Gas business was only moderate, and nearly all in Gaslight “A.” Quotations were unchanged, as also were those for Water stocks. Business in Gas on Saturday did not present any particular feature; but all prices marked were good. Water was wholly neglected.

ELECTRIC LIGHTING MEMORANDA.

THE VALUE OF THE SHARES OF THE LAST NEW ELECTRIC LIGHT COMPANY—THE FINANCIAL CONDITION OF A LONDON ELECTRIC LIGHT COMPANY—FORESIGHT OF A LONDON VESTRY—THE STRUGGLE BETWEEN THE EDISON AND WESTINGHOUSE COMPANIES.

THERE is already wailing among speculators respecting the Metropolitan Electric Light Company, the shares of which were, so the financial newspapers recorded, “jumped at” upon the day of issue. The subscription list was only open for one day; and the “ground bait” in the shape of newspaper articles commendatory of the prospects of the adventure having been judiciously used, the consequence was that some people applied largely for shares, believing that they might possibly get a few. To their surprise and chagrin they were taken very largely at their word. One individual who signs himself “A Miserable Investor” has published a letter complaining how he applied for a large number of shares, expecting to get perhaps one-tenth, and was surprised to receive an allotment of nearly three-quarters of his application. The best of the joke, however, was to come. An hour or two after receiving his letter of allotment he sent to his stockbrokers to inquire the value, and was informed that the shares were at 10s. discount—meaning, of course, that this sum, which he paid on application, had been thrown away. Next day they went to 15s. discount; and at the time of writing his letter the injured one found that they were quoted at 30s. discount, “quite nominal.” Our financial contemporary *Money* remarks that this little affair carries its own history written upon its face. We should add that it also preaches its own moral. The “Miserable Investor” was the cause of his own misery—a condition of human life which is constantly recurring, but which is none the less exasperating on this account. It is evidently a case of overreaching speculation recoiling on itself. It is all very well now for the victim of an artfully-prepared scheme for getting hold of the money of the public to describe himself as an “investor.” There is, however, very little of the air of genuine investment about this bit of business. For the rest, it looks very likely that the successful launching of the South Metropolitan Electric Light Company’s shares, and the present condition of the unfortunate subscribers, will check that revival of interest in this class of stocks which the advent of the Company was supposed to signalize.

An electric lighting concern which has been cited upon different occasions as being in a very promising condition technically and

financially, is the Kensington and Knightsbridge Electric Lighting Company, Limited—at least, this appears to be the full name of the lighting installation which has begun operations in the select neighbourhood of Kensington Court. But according to the last statutory return of the Company it appears that, whereas the nominal capital is £250,000 in £5 shares, only 6020 shares have been taken up. Of these 5000 are considered as fully paid, and probably represent the contractor's interest, while upon 400 shares £5 has been called, and £3 per share upon 620 shares. The calls paid amount to £3060, and unpaid to £800. If this is the best that Kensington can do for the electric light in its midst, it does not look very promising for its prospects in less wealthy neighbourhoods, whatever the electric lighting journals may say respecting the admirable result of the experiment.

The Vestry of St. James's have evidently determined to take a leaf out of the book of the Municipality of Paris, for they have resolved that they will "not approve of any concession or licence being granted to any electric light company to supply such light to the parish, unless the licence provides that, after the shareholders of such company have received an annual dividend of 10 per cent., one-half of the surplus shall be set aside and applied towards the funds of the parish, or in diminution of the charge for lighting by electricity the public streets." It is to be hoped that no harm will happen to the streets of St. James's until this provision comes into force. The indebtedness of the Vestry to the Paris Municipality for the idea is obvious. It might, however, have been thought that, before putting such a resolution upon their minutes, the Vestry would have inquired how the arrangement works in the city where it is actually in force in connection with the gas supply. If they had taken the trouble to satisfy themselves upon this point, they would probably have been less eager to adopt and publish the resolution.

The two most celebrated and successful systems of electric lighting by incandescence—the Edison and alternating transformer systems—are about to be placed in sharp competition in the City of New York, where the Westinghouse licensees are building a large station to compete with the Edison Company. In connection with this rivalry, a strong attempt is being made to prejudice the public mind, and to induce the authorities to take action against the introduction of the high potential currents employed in the Westinghouse system, upon the ground that they are dangerous to life. With this view, a long list of fatalities caused in America by the strong currents (whether used in connection with arc lighting or otherwise) during the last twelve months, has been prepared and laid before the New York Board of Electrical Control, who have been rather alarmed by this statement. It has, on the other hand, been pointed out that the appalling frequency of fatal accidents in the United States from electric lighting currents is traceable to the makeshift and cheap manner in which so much of this class of work is done there, and which would not be tolerated anywhere else. Physiological experiments with electrical currents of high potential have been instituted upon living animals, in order to obtain light upon the question; but beyond the infliction of a great deal of pain upon a number of unoffending creatures—less with a view to the interests of true science than in those of advertising electricians—nothing has come of them. It has been ascertained that an alternating current of about 250 volts will kill a large dog; and it is supposed that a man would have been killed under the same circumstances. But no decisive action has been taken upon these revelations. The authorities are afraid of discouraging a fresh development of electric lighting enterprise upon experimental evidence which, whatever its intrinsic value, comes before them with the taint of trade rivalry; and although the regard of the average New Yorker for advertisement in business is unbounded, he is a humane man, and the suspicion that dogs are being tortured to serve the interests of the Edison Company, will not tend to make him love them more, or to favour their rivals less.

SPIRAL-FRAMED GASHOLDERS.

THE question of the guide-framing of gasholders is decidedly occupying the attention of engineers at the present time—a consideration that is forced upon one by various signs; the latest being the paper read before the Manchester District Institution of Gas Engineers by Mr. T. Newbigging last Saturday, and which will be found in another column. The object of the paper was to bring into prominence a new suggestion for the guiding of gasholders from the base (dispensing with all superstructure for this purpose), which has been offered by Mr. William Gadd, of Manchester, who has apparently been studying the subject well since Mr. W. H. Y. Webber's paper, read at last year's meeting of The Gas Institute, appeared in our columns. Mr. Gadd joined in the discussion this paper elicited in the JOURNAL; and he made some very pertinent observations upon Mr. Webber's proposals. He has now ventured to formulate a device of his own, with practically the same object in view, and has gone even further than anybody who has yet attempted to solve the problem—with what practical success time will show. It is almost certain that his proposal will meet with many adverse comments, besides the dead weight of passive obstruction which all novelties of such a daring character must encounter. Our redoubtable correspondent who writes under the *nom de plume* of "Theory and Practice" will most probably give him a raking fire of criticism; and querists will not be wanting to echo the cry of "*Cui bono?*" which is so convenient in these controversies. For it must not be forgotten that those who advocate a new departure of this nature have all their ground to make good

before they can advance. Engineers accustomed to the established order of things want to know, in the first place, what is to be gained by way of compensation for the risk of abandoning tried methods of construction for something which they are perfectly right in regarding as the fruit of a theorist's brain. It is possible to make this inquiry in perfect good faith—not incuriously condemning theory as such, but asking it to make good its credentials before being accepted as a safe guide for practice. It will be well to grant in advance the existence of this good faith, in order that discussion may be void of recrimination.

First, then, let us understand what is to be gained by such an endeavour as that in which Mr. Gadd has embarked, under Mr. Newbigging's patronage, and in which he follows other daring innovators. It is well that the question has been put forward this time under the hand of an experienced gas-works constructor; for Mr. Newbigging is able to place upon record some data which it is necessary to bear in mind. He shows that in comparatively small gasholders the actual weight of metal in the ordinary kinds of guide-framing above the tank is nearly equal to, or even exceeds that of the holder itself. The proportion decreases with the increasing capacity of the holder, under certain circumstances, although this rule is not invariable; and indeed it is only in the last entry of Mr. Newbigging's table that this becomes apparent. It would perhaps be safer to say that the proportionate cost, rather than weight, of the external aerial guide-framing becomes smaller as holders increase in magnitude, from the fact of the heaviest guide-framing being largely composed of cast iron, costing less than half that of the wrought iron of the floating portion. Owing to this consideration, it may be found that Mr. Newbigging's estimate of a saving of 50 per cent., to be realized from the abolition of what we may term the superior guide-framing of a large holder, is rather excessive. His statement may be found to right itself in this respect, however, in cases where carriage constitutes an important element in the cost of works of this class. And, on the other hand, if the proportionate cost of guide-framing is lessened with the bulk of gasholders, the time occupied in erecting and adjusting it increases; so that there would not be half the trouble and delay in getting new holders into work if the superior guide-framing were dispensed with. There are few gas managers of lengthened and varied experience to whom this latter consideration does not appeal strongly. To sum up, then, a saving of nearly half the cost and quite half the time and trouble in the erection of gasholders is ample justification for the pains of those who seek to tell us how the superior guide-framing may be rendered unnecessary for gasholders. There is, of course, a way of looking at the question in which the possible economy may be made to appear insignificant. It is only a few more tons of iron to put up, while the job is in hand; and it does not work out to very much on the total cost of providing storage for every 1000 cubic feet of gas. But this is not an engineer's view of a structure. To the thorough constructor, every superfluous ton of iron is not only abhorrent as so much "matter in the wrong place," its presence is an element of weakness in the structure, since, if unnecessary, it is probably harmful; and it must always require a similarly unnecessary expenditure for maintenance and keeping in order. All these reflections must occur to every constructor when he is told of a way by which the ends he is accustomed to provide for in a certain manner may be gained by a shorter route.

Briefly stated, Mr. Gadd's suggestion is that a gasholder will sustain itself by its bottom guide-rollers alone, if the guides in which these work are disposed spirally in the tank, instead of vertically after the ordinary fashion. As Mr. Newbigging remarks, the idea is very simple; and he adopts it unhesitatingly, as it is illustrated by Mr. Gadd's models. It must be confessed that such a proposal for getting over the difficulty is enough to take away the breath of an old gasholder builder; but the subject is too important to be lightly treated, still less ridiculed on account of its apparent outraging of all precedent. Let us, therefore, examine the plan for what it is worth. It is obvious that if a gasholder is guided (say) in two spiral channels placed opposite to each other in the tank, any overturning movement (from wind) on the part of the holder—supposing this to take effect along the diameter passing through the rollers—would make the windward one bear against the upper flange of its channel, while the leeward one would bear against the lower flange of its channel. Multiply this action all round the curb by the number of rollers and channels, and verticality is ensured. All this is clear enough from a model. It must be ascertained, also, that the holder would not have any tendency to screw itself out of its guide-channels; but this it could scarcely do. Granting, therefore, that Mr. Gadd's prime object of securing verticality of the floating vessel by his system of spiral guides is secured, as proved by models—and Mr. Newbigging's testimony should be conclusive on this head, even if the models had not been shown to the members of the Manchester Institution—it may be asked what remains to be proved in order to obtain general acceptance of his suggestion?

There are several points to be settled, which can hardly be taken from models. Granted that a holder thus guided will be maintained vertical, notwithstanding its own instability and the effect of wind, it follows that the entire scheme of its system of internal stays must be reconsidered. A very much stronger bottom curb would be required, which might be provided without a great additional weight of metal; and this would have to be firmly connected to the top curb, not merely by vertical stays (for which there would be less need than under the existing system), but also, and more particularly, by spiral ties. It would be necessary

to make some provision for transmitting to the bottom curb all the strains called into existence by the new system by means of stout members made for the purpose, and so taking all of them off from the side sheeting. Unless this requirement were attended to, even if the holder did not fail from buckling, it would be impossible to keep it from leaking, owing to the shifting of the sheets and rivets under the strains along the sides. Then it must be considered that to make a holder revolve on its vertical axis during its inflation, means a certain amount of friction in the guide-rollers; and this again means additional work for the exhaustor. What amount of mechanical work is involved in causing the last holder of Mr. Newbigging's examples, weighing 107 tons per 120 feet diameter, to travel along a path inclined at an angle of 45° under the conditions, as to fit of the rollers, &c., to be expected in the circumstances? We say nothing about any difficulty of making the spiral channels, and fitting the tangential bottom rollers into them, as these are matters that would not dismay a good gasholder builder if he once undertook to make a thorough job of the work. And one is compelled to ask the other questions very much in the dark; for the whole proposal is of such an extraordinary character that judgment must be suspended upon all the points left unsettled by Mr. Gadd's models.

Here, therefore, we must leave the subject for the present; only congratulating the Manchester District Institution upon having had before them such an interesting paper, over which the individual members may be pardoned for shaking their heads many times before making up their minds respecting the matters of which it treats. Mr. Newbigging must be credited with having the courage of his convictions in fathering such a proposal; and it is only what is due to his reputation to treat his remarks upon the subject with respect. It is possible that we may have to wait long for the first realization of Mr. Gadd's project, since a new departure of this kind can only be made at considerable expense, which many people will hesitate to incur for the sake of an experiment. Yet, under favourable circumstances, a proof of the theory upon a sufficiently convincing scale should not be extravagantly costly. These are matters, however, upon which it is not our province to decide. If words mean anything, Mr. Newbigging is pledged to help Mr. Gadd, to the utmost extent of his power and opportunities, to carry out his novel project—unless, of course, the full light of discussion which will now bear upon it should reveal some fatal objection which he has overlooked. His statements are sufficiently explicit upon this point. He emphatically describes Mr. Gadd's device as, in his own belief, "a successful attempt" to solve the problem of dispensing with the superior guide-framing of gasholders without sacrificing anything of the safety of these vessels, and, of course, without detriment to their fulfilling the object of their existence. This is a bold position for an eminent Consulting Engineer to take; and we may be sure that Mr. Newbigging has counted the cost and weighed the responsibility he has assumed in regard to the subject. The proposal thus stands on a different footing to that which it would have occupied if the communication had been Mr. Gadd's paper, explaining his own ideas. As such we have discussed it, in the belief that the matter is not destined to end as merely an interesting portion of the transactions of the Manchester Institution. For a complete novelty in engineering construction of the kind, it has been put forward under very weighty recommendation; and it should be dealt with as a very practical and serious proposal. We have no desire to place upon Mr. Newbigging's shoulders more responsibility in regard to the proposal than he desires, or than his words warrant; but in insisting upon the gravity which his sponsorship has imparted to it, and which is not an idle compliment to him, we are convinced that we do no more than what we shall be supported in by public feeling.

THE Toulouse Gas Company are about to light the theatre in that city with 1000 incandescent electric lamps of 10, 16, and 20 candle power, distributed in two circuits, and so arranged that should an accident happen to one circuit it would not lead to the extinction of the light in other parts of the building. Each circuit is supplied by a 500-lamp dynamo, worked by a double-cylinder "Otto" gas-engine of 50-horse power. The engines are fixed outside the theatre, but at a short distance from it, in an underground chamber. They are of special construction, and have been made by the Company. The incandescent lamps have been attached to the old gas-fittings; and the work has been carried out entirely under the direction of M. Ernest Brouardel, Manager of the Centre and South of France Gas Company.

It has of late been discovered, says the *Scientific American*, that flowing wells of water can readily be obtained by boring in all that part of Utah lying northerly about 100 miles and southerly about 200 miles from Salt Lake City, and in the San Pete Valley. This part of the territory is thickly settled. Towns of from 500 to 5000 population are numerous; and farmers and town residents are availing themselves of this abundant and easily obtained supply, to the partial neglect of the old method of irrigating ditches. A good flowing well will irrigate five to six acres, saving the expense of a yearly water-tax, and having the water daily at command, to be turned on or off as desired. Nearly every residence in the beautiful city of Provo has its own artesian well, part of which is frequently utilized in a fountain in the front yard, throwing a copious jet 30 feet into the air; while hydrants are stationed at intervals in the garden, barn, and elsewhere about the grounds. These wells are being rapidly extended.

Technical Record.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.

The Seventy-fifth Quarterly Meeting of this Institution was held at Doncaster on Saturday last; and more than usual interest attached to the proceedings from the character of the communication made by Mr. T. Newbigging on the subject of "Gasholders without Upper Guide-Framing," to which more particular allusion is made in our "Essays" columns to-day. Before the business commenced, the members had luncheon together at the Elephant Hotel; and afterwards adjourned to the Council Chamber at the Town Hall (which was kindly lent for the occasion by his Worship the Mayor, Mr. Alderman Wainwright), where the business was commenced under the presidency of Mr. Thomas Duxbury, of Darwen. The minutes of the last meeting having been read by the Honorary Secretary (Mr. Harrison Veevers, of Dukinfield), two new members were elected—Mr. Tom Settle, Manager of the Gas-Works, New Mill, near Huddersfield; and Mr. William Drewry, Manager of the Gas-Works, Cleethorpes. Thereafter the President took the opinion of the meeting as to whether Mr. Newbigging's paper should be the next business, or the adjourned discussion on Mr. Dalgliesh's paper read at a previous meeting. It was almost unanimously agreed to take the former course; the members doubtless being largely influenced by the fact that not only had Mr. Newbigging arranged for two models to be prepared to illustrate the paper, but that Mr. Gadd, whose invention was to be described, was present, and would thus be able to answer any questions on the subject of his arrangement. The text of the paper is given on the opposite page; and after it had been read, and the working of the models duly explained, a series of questions was addressed to Mr. Newbigging and Mr. Gadd, which led to further interesting information being given. A hearty vote of thanks to Mr. Newbigging, for the trouble he had taken in bringing the matter before the Association, having been passed, it was determined to further adjourn the discussion of Mr. Dalgliesh's paper till the next meeting of the Institution, to be held in November, as Mr. Dalgliesh (who was unable to be present on Saturday) was desirous of supplementing his original paper by some further remarks before the subject was open for debate. Mr. Dalgliesh's supplementary paper is given to-day in another column (p. 374). Before concluding the proceedings, a vote of thanks was accorded to the Mayor of Doncaster for his courtesy in placing the Council Chamber at the disposal of the members for their meeting. At three o'clock, conveyances were in waiting to take the members and a considerable number of friends to view the ruins of Conisbro' Castle, some five miles from the town; but time did not permit of any very extended stay there, as, from the early hour at which the return trains were due to leave Doncaster, it was necessary to complete the items of the programme at a somewhat early hour. The members therefore assembled for tea directly on their return; the main body leaving for Manchester by the 7.40 p.m. train. After tea, a few complimentary toasts were given; among others a special vote was passed to Mr. R. Bridge, the Engineer of the Doncaster Corporation Gas-Works, for his courteous reception of the members, and the trouble he had taken, in conjunction with the Committee of the Association, to render the meeting, as it was, a pronounced success.

THE Boston (U.S.A.) Gas Company have agreed to supply gas for public purposes in Boston proper (during the next five years) at the rate of \$1 per 1000 cubic feet. The old agreement requires the payment of \$1.20.

WE learn that an amalgamation between the Sanitary Institute of Great Britain and the Parkes Museum has taken place, and that the objects of the two societies will in future be carried on by the Sanitary Institute, which has lately been incorporated.

In a circular just addressed to the Council of the London Municipal Reform League, the Chairman (Mr. J. F. B. Firth, M.P.) points out that among the questions which are "ripening for solution" are increased powers to the new Municipal Council for London to be created under the Local Government Act, so as to bring under their jurisdiction the gas and water supply of the Metropolis.

MR. WEBSTER, whose system of sewage treatment has been already referred to in the JOURNAL, has found, since filing the specification of his patent, that the employment of positive electrodes made of any other material than iron is of little or no practical value in treating sewage and similar impure liquids. He has therefore filed an amendment limiting the patent to the use of positive electrodes of iron, except in the case of the filtering process.

THE result of the investigation by the Finance Committee of the Salford Corporation of the matters referred to them in connection with the Town Clerk's tendered resignation, of which mention was made in our columns last week, has been the suspension of this official. The charge against him is one of misappropriating moneys which he has received on account of registers of voters, and which he should have paid over to the Borough Treasurer. The matter is causing considerable excitement in the borough, especially as Mr. Graves has disappeared.

GASHOLDERS WITHOUT UPPER GUIDE-FRAMING.

By THOMAS NEWBIGGING, of Manchester.
[A Paper read before the Manchester District Institution of Gas Engineers, Aug. 25.]

A valuable paper on "The Guide-Framing of Gasholders" was read by Mr. W. H. Y. Webber, of London, at the meeting of The Gas Institute held in Glasgow in 1887.*

In treating of the subject, the author did not advocate or suggest any new principle of guiding the structures in question, but contented himself with endeavouring to show that, by a modification of the ordinary arrangement of bottom rollers (which he proposed to duplicate and strengthen, to bear the extra strain which would be thrown upon them), and by the addition of tangential rollers, the upper guide-framing, or the greater portion of it, might be dispensed with. The present paper is intended to describe a recent invention of Mr. William Gadd, of Manchester, whereby an entirely new principle is introduced, by the application of which a gasholder may be securely guided from the bottom curb; the whole of the elevated framing being done away with, whilst at the same time the strain of wind or snow pressure upon the holder has the effect of producing greater rigidity in the structure. How this is accomplished I will explain immediately.

The weight of the guide-framing of gasholders, as usually designed and constructed, if composed of wrought-iron standards, slightly exceeds that of the floating vessel; and if of cast-iron columns, the weight of the framing is greater still. It follows, therefore, that the cost of the guide-framing of a holder amounts to about one-half the cost of the complete structure.

I have various recent examples of gasholders and their guide-framing, which I have put together in the form of a table, which may be quoted in support of this position.

Description.	Weight of Holder or Bell.	Weight of Tank Guide-Framing.	Weight of Upper Guide-Framing.	Total.
	Tons.	Tons.	Tons.	Tons.
Single-lift holder, 50 feet dia., 16 feet high.	18	3	17	38
Do., 72 feet dia., 18 feet high.	44	5	40	89
Do., 80 feet dia., 20 feet high.	47	5	50	102
Do., 80 feet dia., 28 feet high.	49	9	53	111
Two-lift telescopic holder, 80 feet dia., each lift 20 feet high.	70	6	82	158
Do., 80 feet dia., each lift 20 feet high.	61	7	70	138
Single-lift holder, 100 feet dia., 24 feet high.	66	7	75	148
Two-lift telescopic holder, 120 feet dia., each lift 24 feet high.	107	12	86	205

Now, such being the facts, it is evident that if the upper guide-framing of a gasholder could be dispensed with altogether, and equal or greater stability and safety in the rise and fall of the floating vessel secured, a saving of about 50 per cent. would be effected in the cost of construction and erection. An attempt—and, as I believe, a successful attempt—to secure this condition of safety, whilst dispensing with the elevated framing of gasholders, has been made in Mr. Gadd's invention—two models of which I have the pleasure to submit. Like most important inventions, the means for attaining the end contemplated are as simple as they are effective and beautiful. So simple are they, indeed, that the excellence of the invention will be obvious at a glance; and the first thought that strikes us on examining the models is one of wonder that the expedient has never been thought of before.

Briefly stated, the invention for dispensing with the elevated guide-framing consists in placing the channel or other guides within the tank at an angle, like the thread of a screw, instead of in the vertical plane, as has hitherto been the invariable practice. The guide-rollers attached to the bottom curb of the holder are ranged either radially or tangentially with the sides of the vessel; and as they work in the channel or rail guides provided for them, a helical or screw-like motion is communicated to the floating vessel as it rises and descends in the tank. The arrangement is shown in the accompanying figure.

The guides attached to the tank sides may be placed at any angle from 45° upwards. In the models before you they are fixed, one at an angle of 45°, and the other at 60°, which latter is probably the most suitable for single-lift holders. The effect of thus arranging the guides is obvious. So long as the rollers are free to move within the guides, it is impossible that the holder can tilt so as to get out of the vertical; the tendency of wind or other pressure exerted against the sides or on the roof of the vessel being to produce what may be described (imperfectly, however) as a locking action, which will sustain the holder in the upright position, however great the strain, whilst the resisting strength of the rollers and their carriages. Whilst this locking or gripping action gives rigidity to the vessel, enabling it to resist the overturning force, the rollers are perfectly free to rise and descend within the guides.

Adopting Mr. Webber's description—and I see no reason to question its accuracy—that the gasholder, as at present constructed, may be compared to a pole whose lower end is placed in

a socket, though not resting on a base, it may be pointed out that it is just the absence of this bottom bearing which accounts for the inherent weakness of such structures. It will be seen, however, that the holder, as now proposed to be guided, has almost as positive and substantial a bearing as it would have if lifted bodily out of the tank and placed upright on the ground. It is in this that the chief value of the invention consists; for at the present time the tank-guides, owing to their vertical direction, afford no actual security against tilting—their only office being to prevent the swaying of the vessel to and fro when under stress of outside pressure.

It is evident, further—and this is a most important consideration—that immediately the strain comes upon any part of the holder under the new conditions of guidance, the resisting action of the whole of the guides, both front, back, and sides, is brought into operation, one-half the rollers being in tension and the other half in compression; and the vessel is literally held with (to use a paradoxical expression) a grip rigid yet loose.

It will be seen, therefore, that by the proposed new method of construction, the guides within or upon which the bottom rollers work, answer not merely the purpose of guiding the vessel in its rise and fall, but also serve as cramps or grips, withstanding, by their locking power, whatever strain may be exerted against the holder, whether laterally on the sides, or perpendicularly upon the roof. As a matter of fact, the effective capability to resist strain—assuming that the floating vessel and its trussing are sufficiently strong—is only limited by the strength respectively of the guides and that of the carriages and rollers.

It may be suggested that a holder thus guided and kept in the upright position solely from the base, will need to be strengthened in the upper curb, so as to overcome the crushing force exerted by wind on the sides. A moment's consideration, however, will show that this is not necessary. As at present constructed and guided, gasholders are capable of resisting the maximum crushing strain that is exerted by the greatest wind pressure upon their exposed side—i.e., a pressure equal to 20 lbs. to the square foot exerted upon a plane represented by 50 per cent. of the area of vertical transverse section of the holder. The elevated framing does not relieve the crushing strain in any degree; on the contrary, it assists or aggravates it by presenting a rigid support to the leeward side of the vessel. I should scarcely have mentioned this, had it not been urged as an objection.

The only possible danger that can arise is that of distortion or dislocation; and this can readily be obviated by giving the vertical supports or stays inside the holder more of the form of a girder than at present. Probably the triangular form, with the base of the triangle at or near to the bottom curb of the holder, would be the best. These would receive the strains exerted against the sides and roof of the vessel, and transmit them to the bottom curb and rollers, and thus secure the stability of the whole. It will be urged as an objection to this that the effect will be to add weight to the holder which was previously in the guide-framing. Any such addition, however, if required, will be trifling as compared with the weight of the guide-framing as at present constructed, and will be very far from neutralizing the economical advantage of dispensing with this framing altogether.

With the exception above noted, there need be no change in the mode or materials of gasholder construction. It is not unlikely that steel may be employed more generally in these structures than heretofore; and this, whilst allowing a reduction in the weight, will greatly increase the power of the trussing to resist strain from outside.

It may be pointed out that the probable cause of most of the accidents which have arisen in the overturning of gasholders under wind pressure was owing to the want of rigidity in the bottom carriages and rollers, allowing of the swaying to and fro of the floating vessel, thus causing sudden impact against the vertical columns, which have been snapped off by the blow; and the holder, being guided at neither top nor bottom, has been overturned by the wind. It is one of the chief merits of the present invention that rigidity of the rollers is secured as a natural consequence of the method of arrangement of the guides; and is not dependent on either the skill or the attention of the workmen employed in construction and erection.

The ordinary method of counterbalancing gasholders, where counterbalancing is required (as in the case of holders whose

* See JOURNAL, Vol. L., p. 171.

diameter is small when compared with their depth), will not be necessary under the proposed system; for the same result will be obtained by increasing the length of the roller path, by placing the guide-rails in the tank at a less angle.

Perhaps it will be suggested that, with the tank-guides constructed and fixed as described, there will be difficulty experienced in raising the holder for repair when the water is out of the tank. This objection has no force. All that is required under the new conditions is to arrange the lifting screws and chains so that the pull will be in a slanting direction, when the vessel will be raised with as much ease as at present.

Exception may be taken to the invention from an æsthetical point of view. It may be urged, with some show of reason, that the only possible ornamentation in connection with a gasholder is supplied by the elevated guide-framing, and that wanting this the floating vessel standing above ground without apparent support will be a somewhat ungainly object. True, the holder might be ornamented round the top ring with palisade or open chequer-work; and other methods of ornamentation may be adopted. Whether this be so or not, however, appearance will not weigh for one moment with those who are concerned in providing the capital required to be expended on such structures; and neither ought it to do so, when the advantage in the saving of cost is so manifestly in favour of the proposed method of construction. This saving is not confined to the ironwork of the holder, but extends also to the underground tank. The necessity for the provision of piers or counterforts, and large and expensive foundation-stones for the bases of columns or standards, will disappear; the tank for such a holder being cylindrical both inside and outside the walls, from base to summit. Again, in the case of holders made for shipment abroad, there will also be the saving of about 50 per cent. effected in the cost of freight. In these days of active rivalry in the methods of artificial illumination, whatever improvements tend to keep down the capital of a gas-works will be welcomed.

NEW GAS MAP OF LONDON.—Mr. Preston Davies has just completed a new map of the Metropolitan and Suburban Gas Companies' districts, in the preparation of which he has had the assistance of the Engineers of the several Companies whose limits are defined. These are: The Gaslight and Coke, South Metropolitan, Commercial, Harrow, North Middlesex, Hornsey, Tottenham and Edmonton, Lea Bridge, West Ham, West Kent, Bromley, Crystal Palace, Mitcham and Wimbledon, Wandsworth and Putney, Richmond, and Brentford. The map has been arranged for the addition, if required, of the districts of the remoter Companies lying around the Metropolis.

PRESENTATION TO MR. WM. W. GRAY, OF CAMBRIDGE.—Last Thursday afternoon, the *employés* of the Cambridge University and Town Water-Works Company presented to the Manager, Mr. William W. Gray, a testimonial, in the form of a silver-plated biscuit-box, suitably inscribed, as a mark of their appreciation of the kindness they had always received at his hands. In accepting the testimonial, Mr. Gray alluded to his long connection with the Company, which, he said, extended over a period of nearly 23 years; and he remarked that, as they all knew, his first object was the success of the undertaking. In studying that, they were really benefiting themselves. Before the presentation, the *employés* and Mr. Gray took tea together; and the proceedings altogether were of a very pleasant character.

EXTENSION OF GAS SUPPLY IN SOUTH AMERICA.—We learn from an esteemed correspondent that the new gas-works which are about to be constructed at Buenos Ayres, under the supervision of Mr. G. E. Stevenson, Assoc. M. Inst. C.E., will be the largest yet built in South America, and will be capable of manufacturing 1½ million cubic feet of gas daily. The Company which is going to start the works and compete with the existing undertakings is quite a local one, and is on the co-operative principle. The shareholders are gas consumers, and will get 10 per cent. reduction in the price of their gas. The works are being put up by a syndicate, whose intention is to build a number of works in the country. Besides those at Buenos Ayres, they expect to erect others at Rosario, the town of next importance in the Republic, having 70,000 inhabitants. The works there will have a capacity of 600,000 cubic feet per diem. In the town of Paraná, the capital of the province of Entre-Rios, works are to be constructed capable of turning out 100,000 cubic feet of gas daily. These are all indications of a satisfactory extension of gas supply in South America.

RUST ON IRON.—At the meeting of the Iron and Steel Institute in Edinburgh last week, Professor A. Crum-Brown gave a description of the chemical processes involved in the formation of rust on the surface of metallic iron exposed to ordinary atmospheric conditions. He said that iron remains quite free from rust in an atmosphere containing oxygen, carbonic acid, and water vapour, as long as the water vapour does not condense on the surface of the iron. They could follow the whole process of rusting, and divide it into stages; these stages being really separate, if they took proper precautions. When once the process was started, it went on more rapidly, because the porous rust not only did not protect the iron, but favoured, by its microscopic character, the condensation of water vapour from the air as liquid water. A piece of iron, therefore, which has begun to rust will continue rusting in an atmosphere not saturated with water vapour—an atmosphere in which a piece of clean iron would not rust—because the liquid water will condense on the microscopic rust from such an atmosphere, but not on the bright iron.

OIL AND OTHER ILLUMINANTS, AND THEIR EFFECT ON THE CONSUMPTION OF GAS.

By JAMES DALGLIESH, of Glossop.

[Supplementary Paper presented to the Manchester District Institution of Gas Engineers, Aug. 25.]

When reading my paper on this subject at our December meeting in Manchester,* I endeavoured to give the origin of various illuminants connected with artificial lighting—viz., from pine, resinous bark of trees, oily kernel of a nut, fat of animals, and the bitumen and naphthas of the mineral kingdom, in conjunction with a porous material which was provided to be dipped in these luminous combustibles; eventually leading to the invention of the torch, the candle, and the lamp. I also referred to the introduction of our illustrious illuminator of the world—gas; the production and distribution of petroleum oil (its commercial and financial position); and the use of electric light—but as an opponent, gave it as my opinion that oil was the most formidable, owing to its bountiful supply and the means of obtaining it.

I now wish to state a few facts connected with its use; and leave them to tell their own sad tale. A pamphlet circulated by the Hospital Sunday Fund, in June, 1886—entitled, "Within the Hospital Walls"—stated that the House Governor of a London Hospital said: "Every week we have to admit several people suffering from burns and explosions caused by paraffin-lamps; and nearly every week an inquest is held in London on somebody killed by them." Mr. Charles Marvin, who has written largely on the use of petroleum as an illuminant, says "that it is notorious that in every country the increase in the use of petroleum has been accompanied by an increase of accidents; and it was not surprising that I should feel saddened, that, in promoting a larger use of petroleum by my writings, I had at the same time multiplied death and disaster!" About the spring of the year named—on the steamer *Vaira* on the Volga—a paraffin-lamp accident caused the loss of more than 100 human beings. The baths at Scheveningen were burnt down through a paraffin-lamp; and Hampton Court narrowly escaped a similar fate. Captain Shaw, of the London Fire Brigade, says that 10 per cent. of the fires are caused by the paraffin-lamp. On Oct. 18, 1871, a cow accidentally kicked over a paraffin-lamp in a wooden shippin, setting the structure on fire; and the wind speedily carried the flames to an adjoining timber-yard on the banks of the Chicago River. From thence they spread through the whole city, destroying 20,000 buildings, and making 100,000 persons homeless. About 250 persons perished in the flames; and it cost Chicago a sum of nearly £60,000,000.

Throughout the United Kingdom, most distressing accidents and deaths are almost daily recorded in many of our valuable journals; and yet the consumption of paraffin and petroleum oils continues to increase. True, in numerous houses, where the poor of our large towns and cities dwell, there is no provision made by the landlords for the use of gas. There are hundreds, and in some towns thousands of houses where there are no gas-fittings, and the tenants are of such a character that it would be unwise to trust them with a quarter's gas supply; and these go to increase the percentage not using gas. Most of this class used to burn candles, and no doubt have recently substituted petroleum oil as their illuminant. If it had been possible for the engineers and managers of the various gas companies and corporations to have furnished me with the actual number of houses not fitted up for the consumption of gas, and the number with defective fittings, they would have shown gas in a more correct light. In my own district, hundreds of houses are without gas-fittings, and hundreds so wretchedly "hung"—not fitted—with ½-inch gas-pipes, and the rest to match, that tenants cannot use them. I do not think there is a district in the United Kingdom with such bad internal fittings—apologies for fittings; and when before the Committees of the House of Commons and the House of Lords in 1879, seeking for additional capital, &c., the writer exhibited numerous curiosities called gas-fittings, which greatly astonished even the opponents of the Bill.

In the towns shown in the table given with my former paper, where the consumption of gas is from 2,000,000 to 6,000,000 cubic feet per mile of main, there should not be much difficulty to cope with oil or the electric light; and the engineer must be a happy man. But where the consumption is only ¼ to 1 million cubic feet per mile, with 50 to 60 miles of mains and a hilly district, it is a difficult task, particularly when he has always to provide maximum dividends, good gas, &c.—all has to be good, but the manager's salary.

Notwithstanding our numerous difficulties, and the evil times, it is our duty to advance the interests of our shareholders or the ratepayers, as the case may be, and still exclaim: "Heave away, lads, we're not dead yet." Let us hope that good may come out of evil.

THE WATER SUPPLY OF NEW YORK.—The Commissioner of Public Works of New York states, in discussing the water supply of the city, that although 110 million gallons are supplied daily, the increase in consumption has reduced the head 4 feet. In order to economize until the new aqueduct is in operation, the meter system is being rapidly extended. There are now 16,532 meters in use, accounting for 24 million gallons, for which the city receives £164,588. If the whole of the supply were metered, the city should receive at least £1,000,000 per annum, instead of only a little over £500,000.

* See JOURNAL, Vol. L., p. 1091.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

OFFICIAL REPORT OF THE PROCEEDINGS AT THE ANNUAL MEETING IN GLASGOW.

We conclude to-day the publication of the report of the proceedings at the above meeting, commenced in the JOURNAL last week.

On the reassembling of the members after the adjournment for luncheon, the first business was the reception of the report of the Scrutineers (Messrs. J. Cameron, of Glasgow, and A. Mackenzie, of Edinburgh) of the balloting-papers. It showed that the undermentioned gentlemen had been elected as the

OFFICE-BEARERS FOR 1888-9.

President—George R. Hislop, Paisley.

Vice-Presidents—Samuel Stewart, Greenock; R. Robertson, Bathgate.

Secretary and Treasurer—Robert S. Carlow, Arbroath.

Auditor—D. Bruce Peebles, Edinburgh.

Committee—J. M'Gilchrist, Dumbarton; J. Adam, Pollok-shaws; T. D. Hall, Montrose.

Mr. HISLOP: Allow me to thank you all or placing me in the President's chair for the next twelve months. I was inclined to shrink from the responsibility of conducting the affairs of the Association for the coming year. But I must yield to the powerful influence of my friends; and I have to thank you for so unanimously returning me to that position. I shall endeavour, to the best of my ability, to discharge the duties devolving on me as President; and I hope the interests of the Association will not suffer in my hands. I have already been President twice; so that this makes my third election to the presidential chair in twenty years. I was anxious that the duties of this responsible office might have fallen on some other member; but I have yielded to the request of the Association, and I thank you for the honour you have conferred upon me.

PLACE OF NEXT MEETING.

It was agreed to hold the next meeting of the Association at Dunfermline.

MR. KEILLOR'S PAPER.

Mr. G. Keillor (Nairn) read a paper on "Automatic Gas Lighting." This will be found in the JOURNAL for the 7th inst. (p. 246).

Discussion.

The PRESIDENT: Mr. Keillor has succeeded admirably in overcoming the difficulties he had to contend against in lighting the pier-head lamp at Nairn. He did not mention that the pier is 200 feet long; and that the lamp is 500 feet distant from the main, and is raised to a height of 30 feet. You can readily imagine the difficulty of getting along the pier during a storm, when the waves are dashing over the masonry; and I think Mr. Keillor has managed very well to surmount the difficulty. Looking at the matter from a pounds, shillings, and pence point of view, I find that it takes about 13s. to keep a flash-light burning for a year, which is the only other way in which automatic gas lighting can be carried out; so that it would cost five or six times as much to keep up a flash-light as it does for the interest on the first cost of adapting the electric appliance according to the plan brought before you by Mr. Keillor.

Mr. T. D. HALL (Montrose): I am sure we are all very much indebted to Mr. Keillor for the able manner in which he has brought this matter before us; and it is doubtful whether there is one here, connected with the gas profession, who does not know of some place which could be lighted by this method more efficiently than is being done at present, especially steeple clocks, where very often the flash-light is not used, but the lamplighter has to climb a ladder or a stair every time the gas is lighted. For harbour and beacon lights, Mr. Keillor's plan would be very useful, and very convenient.

Mr. KEILLOR: I may explain that the station governor has this effect—that there is an arrangement connecting the top wire, which passes a current up the lamp-post to the lighter. The action of the lighter turns the gas on and off by means of a ratchet. The reverse takes place when we reduce the pressure. The governor falls when the pressure had been brought below 12-10ths, and connects the lower wire.

The PRESIDENT: It may be pointed out that the tap (or cock) which leads to the main towards the pier can be opened and shut. If you open the tap at the entrance to the pipe leading to the lamp, you can regulate the light and put it out. A battery can be placed anywhere, so long as you carry the wire to the lamp. One battery is sufficient.

Mr. W. CHEYNE (Briton Ferry): In our place we have to light a range of lamps three miles out at sea. Mr. Keillor's plan would not suit us, because the tide falls 35 feet, and you could not protect the wire.

The PRESIDENT: The battery can be placed above the highest level.

Mr. CHEYNE: Our system of automatic lighting has worked for five years without any trouble.*

The PRESIDENT: How much does it take to light the lamps?

Mr. CHEYNE: It takes 5 cubic feet of gas per hour to supply a flash-light to 12 lamps. The lamps are lighted every tide during the winter.

The PRESIDENT: But the flash-light is very expensive. If the price of gas is 3s. per 1000 cubic feet, and you burn 1-10th of a cubic foot constantly for every flash-jet, it costs 2s. 8d. a year of 8760 hours; if the price is 4s., it costs 3s. 7d. a year. At the rate of 5 cubic feet of gas per hour for 12 lamps—i.e., $\frac{1}{2}$ cubic foot per lamp—if the pilot light is constantly burning, the cost for gas for a year would be 11s. at 3s., or 14s. 9d. at 4s. per 1000 cubic feet. Comparing these figures with the sum necessary for interest on the cost of the electric gas-lighter, which would only be from 2s. to 3s. per annum, it will be apparent that great economy would result by the use of Mr. Keillor's arrangement.

Mr. A. SMITH (Aberdeen): And Mr. Cheyne's arrangement has to light the lamps every tide.

Mr. CHEYNE: The light has to be furnished for the ships coming into the port twice every 24 hours. You could not carry out a wire.

Mr. KEILLOR: The whole of my apparatus can be fitted up in the lamp itself; and when you send the gas to the lamp, the light is ready.

Mr. CHEYNE: But you would require to put a battery on every lamp?

Mr. KEILLOR: Yes; in your circumstances.

Mr. A. MACPHERSON (Kirkcaldy): The thanks of the Association are due to Mr. Keillor for the excellent paper he has brought under our notice. He has arranged his system very ingeniously, and apparently very effectively. In his case I do not suppose it could be better managed; but Mr. Cheyne's method is possibly the most satisfactory in his special circumstances. I have used electricity for another purpose; and it only shows that, if we take advantage of it, electricity, instead of being our great rival, can be made a very obedient servant, and of great use to us. We fill our district gas-holder about a mile from the works; and on the main through which we send the supply I fitted up a little governor. When the gas is shut off, the governor rises and rings an electric bell, and the man knows he has to look to the pressure at once, so that we have the pressure checked without going to see when the holder is filled. By taking advantage of electricity, we may save ourselves a great deal of trouble—in fact, might even use the electric light, just to show the superiority of gas over it. The thanks of the Association are due to Mr. Keillor for the lucid way in which he has described his model.

Mr. KEY (Tradeston, Glasgow): All these arrangements are very ingenious; and the author deserves credit for his ingenuity. In 1873, the late Mr. Abraham Malam read a paper to the West of Scotland Association, at their meeting in Dumfries, in which he described his arrangements for the automatic lighting of street lamps by electricity.* He had a glass cylindrical jar containing an annular glass cylinder, sealed in acid, forming (with carbon and zinc) a battery. When the evening pressure was put on, the gas was admitted to the outer annular chamber; and, acting on the surface of the acid, sent up the liquor in the inner tube, thereby coming in contact with the zinc and carbon, completing the circuit, and causing the gas to be immediately lighted. When the pressure was withdrawn from the mains, the liquor in the outer cell rose, and that in the inner tube lost contact with the zinc and carbon, and the gas was extinguished.

The PRESIDENT: I am sure it will be of great advantage to us to know, should occasion require us to do similar work, that we have Mr. Keillor's example as a precedent to guide us in respect of automatic gas lighting.

MR. M'GILCHRIST'S PAPER.

Mr. J. M'Gilchrist (Dumbarton) next read the paper on "Selling Gas," which was given in the JOURNAL a fortnight ago (p. 287).

Discussion.

The PRESIDENT: You have heard a very interesting paper, prepared and read in his own inimitable way by Mr. M'Gilchrist; and we shall now be pleased to hear any remarks.

Mr. BELL: Does the money turn the spindle of the index of the prepayment meter?

Mr. M'GILCHRIST: This is a case of contracting with the gas company. If a customer wishes to purchase 1000 feet of gas, he pays his money, and the gas inspector turns on the gas. When the quantity paid for has been consumed, the gas is turned off.

Mr. KEY: From the title of this paper, I expected something very humorous and very racy; and I have not been disappointed. No one but Mr. M'Gilchrist could have put his paper in such pleasing phraseology. I think his plan of engaging canvassers, or those who receive a percentage for the collection of money, for the purpose of canvassing for gas consumption, is a very good one. He might have gone a little further, and suggested the wheelbarrow man; for, in the early days of the Edinburgh Gas Company, bags made of leather or other material were filled with gas, and hawked about the streets in a two-wheeled barrow, and sold to one person here and another there for one or two nights' supply. The customers could then see the volume of gas they were receiving. Meters are a great mystery to many people.

Mr. S. STEWART (Greenock): I agree with Mr. M'Gilchrist that there should be small payments, as there would be much more gas consumed if we had them. I do not think it is right to take large deposits. By doing so you prevent many people from burning gas. I know that many people in Greenock do not use gas because they cannot pay the deposit. I do not think we should

* Mr. Cheyne's arrangement, which was brought under the notice of the Association at their meeting in 1883, was described and illustrated in the JOURNAL for March 6 of that year (p. 413.)

* See JOURNAL, Vol. XXII., p. 682.

press people too hard. Of course, a great deal of caution should be exercised; but I cannot understand why gas companies should expect to carry on their business without risk. Ordinary traders do not ask their customers to make deposits; and I do not see the force of gas companies doing it. There is a very strong feeling against meter-rents; and, in my opinion, meters should be supplied free. I agree with Mr. Key that Mr. M'Gilchrist has given us a very able paper.

Mr. G. R. HISLOP (Paisley): I cannot agree with Mr. M'Gilchrist in the matter of supplying meters free; but I maintain that it would be right to charge for them only the annual cost of maintenance. That is as far as anyone can be expected to go in this direction. No doubt the "power of littles" may be made manifest by encouraging the use of gas amongst small consumers. In Paisley we are very lenient in regard to deposits. We exact them from all parties with whom we are not acquainted; but, as a rule, the deposit is returned on the first account being paid. Suppose we take a deposit of 4s., and the consumer burns 4s. or 5s. worth of gas, the amount is deducted at the end of the first quarter; and I think the justification of this course will be manifest when I tell you that our loss from bad debts is only $\frac{1}{2}$ per cent. on the gross revenue. Though the deposit is exacted, the system we go on does not involve any hardship. We "square accounts" generally at the end of the first quarter; but if we are not very sure about the parties, we continue the deposit until the second quarter. It is all settled up, however, before the end of the year.

Mr. A. MACPHERSON (Kirkcaldy): Like the other speakers, I have to congratulate Mr. M'Gilchrist on the able manner in which he has brought this subject before us, and on the admirable way in which he has treated it. I see no objection to canvassing for consumers. Although it may be a little expensive, it would pay in the end. There cannot be any danger in canvassing on the prepayment system, for we should be sure of our money. Many people would gladly burn gas who do not now use it for the simple reason that they cannot pay the quarterly accounts; but if we had monthly accounts, small consumers would make an effort to pay. They could go to the office and pay for a quantity of gas as often as they pleased; and it would be their duty to watch and see when the gas was about to run out. I cannot agree with the suggestion to do away with meter-rents. I do not think the abolition of these rents is fair. Suppose we put a three-light meter into the house of a consumer who burns (say) 5000 cubic feet of gas per annum, and a similar meter into the house of one who burns 10,000 cubic feet, there is the same amount of capital expended in measuring the 5000 as in measuring the 10,000 cubic feet; and it goes on in increasing ratio for the larger consumer. I think a small deposit is very beneficial until we know the customers with whom we are dealing. If a stranger comes to us for a supply of gas, we ask if he has burnt gas before; and unless he can produce a clear bill for his last payment, we exact a deposit of 5s. until he makes two payments, after which the deposit is cleared off by the next bill. There is one thing, I think, which we ought to impress on the people, and that is that we should have the control of the gas up to the point of consumption. My experience within the last few years has been that speculative builders run up houses to sell; and the gas-pipes are simply thrown in. There is no regard to size or anything else; and the tenants are not a couple of months in possession before a complaint is made that they cannot get gas in some part of the house, and that the lights are jumping. Until gas companies make a determined stand, and say they will not supply any gas until they are satisfied that the fittings are proper, there will be no remedy. If we combine to have the control of the supply, or at least to see that the fittings are properly put into houses, our duties will be simplified, and a great deal of extra pleasure and certainly additional light will be given to consumers of gas in general. If ever such an ideal company as Mr. M'Gilchrist has sketched is formed, we shall all know where to get a most efficient and humorous manager—viz., in Mr. M'Gilchrist himself.

Mr. A. DONALDSON (Edinburgh): Mr. M'Gilchrist does not mention any discount allowed to consumers who pay their accounts within a certain period. I think this is a good plan, and has worked well in several places.

Mr. A. SMITH (Aberdeen): There is a large amount of useful information in Mr. M'Gilchrist's paper. It would be a great matter if we could get short payments, the want of which keeps many consumers back. In regard to the supervision of pipes laid in buildings, I may mention that in Aberdeen building is going on rapidly, and that there is no supervision. We have no charge of the pipes, as our duties, according to our Act, cease at the main. The result is that in many cases the pipes are simply thrown into the houses; and the waste and loss to the consumers are very great. The defects are so serious that wet meters have become of no use, and dry meters have to be introduced. I think the gas-supplying authorities should have the supervision of fittings in houses.

Mr. G. KEILLOR (Nairn): In June, 1887, I brought the subject of weekly collection before my Directors. They thought it would be a complicated and troublesome system; but after I explained it, they saw there would be no risk, and that it would be simply a matter of working out. We have a collection-book specially made up with two double money columns. When a consumer commences on the weekly system, we begin to collect. We enter the quantity of gas consumed, and then total up the collection; and at the end of three months, if there is any balance, it is shown on the other side. When I first started, an insurance agent told me he was quite certain it would not be more troublesome to collect

gas-rents weekly than it was to collect insurance premiums. We have 530 consumers, of whom 113 are on the weekly system, and 57 are new consumers. The money collected from these 57 last year was £109. The collector—a young lad—calls twice a week, on Thursday and Saturday, and we pay him 5 per cent. on the amount brought in. He does the whole of the work in three or four hours each week. Our selling price for gas is 7s. 6d. per 1000 cubic feet, less 10d. discount for cash; but no discount is allowed to those who pay weekly. Gas for cooking and heating purposes is sold at 4s. 7d. per 1000 cubic feet; the supply being by special meter, and, as a rule, by a separate service-pipe.

Mr. HISLOP: Does the consumer pay for the hire of the meter?

Mr. KEILLOR: Yes, for lighting purposes; but not for cooking.

Mr. M'GILCHRIST, in reply, said that he thought the subject of weekly payments and consumers' internal pipes and fittings should be taken up by the Committee, who should prepare and present a report to the Association. Something should really be done to draw in more consumers from the class to which he had referred. Twelve years ago he persuaded the Corporation of Dumbarton to adopt a standard of sizes for internal pipes for the supply of houses; and from that period no pipes had been introduced in new buildings in Dumbarton without being inspected by a representative of the Gas Corporation. If they were, upon inspection, found not to be in accordance with the standard of sizes issued by the Corporation, they were turned out, and replaced by pipes of proper dimensions. The general public were grateful for this action of the Corporation. Upon the matter of discounts for early payments, he argued that, when gas consumers had three months' credit, they should not be allowed more than a month afterwards to pay their accounts. Referring next to the question of meter-rents, he said he was sorry that Mr. MacPherson had not been educated up to the point of supplying meters free; but this was his misfortune rather than his fault. Replying to the argument about the unfairness to the large consumer of not charging meter-rents, Mr. M'Gilchrist said the same argument would apply to a railway company, which would, on the same lines, be entitled to charge more for a 20-stone traveller than a 10-stone traveller. In every business difficulties such as these had to be encountered; and they must be overcome. Customers must be treated not altogether on their individual merits, but according to a broad, general principle, which should apply to every class of consumers, and at the same time tend to forward the interests of companies supplying gas. Mr. Hislop had always been antagonistic to free meters; but he (the speaker) trusted that Mr. Hislop would live to see the error of his way. It would, in his view, tend to the advantage of gas corporations if the charge for the meter was included in the price of gas. When the meter-rent prevented people from consuming gas, the manufacturer should, in his own interest, give way. Consumers of gas should be treated in much the same way as traders treated customers. If complaints should be made, rather than make a fuss about the matter, say: "We will allow it." Gas companies should have a little more of the spirit of give and take about them, and should not stick to the hard-and-fast lines of the past. With regard to deposits, Mr. M'Gilchrist contended that if it was left to the option of gas managers to charge or not to charge deposits, it placed them in an awkward position. Supposing a man were to pay his gas account for two years in succession, it did not follow that he was an honest man. The third year he might run up a bill and not be able to pay, or disappear; and the loss had ultimately to be borne by the consumers who paid their accounts regularly. When a man of dishonest habits got into debt, he sometimes felt inclined to go off to another town rather than pay up his arrears. Therefore, he (the speaker), thought that the deposit system was a check which acted in favour of the company or the corporation, and did no harm to consumers because they got more interest on their deposits than they could get in other securities. He had known cases in Dumbarton where the consumer wanted to increase his deposit because it was a good investment. Mr. Hislop, in speaking of the system adopted in Paisley, said it was an argument in its favour that the bad debts amounted only to $\frac{1}{2}$ per cent. on the revenue. Looking to the gas revenue of Paisley, this must amount to a considerable sum per annum. Were Mr. Hislop to adopt the Dumbarton system, this $\frac{1}{2}$ per cent. of bad debts would appear on the other side of the account. Again, gas companies were not like ordinary commercial firms in the matter of customers. The ordinary trader could select his customers, and sell only to such as he approved of; whereas an incorporated gas company must supply gas to every ratepayer who applied for it, irrespective of his financial standing. Mr. M'Gilchrist concluded by saying he was glad that the subject which the President had selected for him had been so well received by the gentlemen present.

MR. SMITH'S PAPER.

Mr. J. Smith (Rosewell) then read a paper on "Regenerative Furnaces for Small Gas-Works." It appeared in the JOURNAL for the 14th inst. (p. 288).

Discussion.

The PRESIDENT: I hope you will enter heartily into the discussion of this subject, which is a most interesting one, and one which is intimately connected with the success or otherwise of a gas company. I trust that those who have a direct interest in, or who intend to adopt a similar furnace, will take part in the discussion.

Mr. ALEX. SMITH (Aberdeen): There is no question that this

gentleman deserves great praise, for he has accomplished a smart piece of work. There is one point to which I wish to direct attention, and that is the position of the producer. It appears to me that he would have some difficulty in taking the clinker off the sides, on account of being so far under the setting. We are told that the cleaning out is done only once in 24 hours. I should have thought it would have had to be done more frequently—perhaps once every six hours. There is no doubt this is a step in the right direction.

Mr. S. STEWART (Greenock): I have to congratulate our friend on his very ingenious arrangement. I approve of the system of having the producer inside. In the Klönne bench we take out the clinker once in every 48 hours; the time depending on the fuel used. If we are careful to choose a fuel containing a small percentage of ash, the clinkering may not be required for a considerable time. Mr. Smith's arrangement is useful, because it allows the use in small gas-works of only a few retorts in one oven; and, what is much more important, it enables them to keep the retorts in heat during the night.

Mr. D. YOUNG (Dalketh): I have visited the Rosewell Gas-Works, and seen this furnace in operation. I went there on a Monday forenoon, when the furnace had not been cleaned out for 60 hours; and in the retort-oven there was a good working heat. I have put in a setting on this principle; and if it produces the same heat, working spent shale and a not very good splint coal, I shall be well satisfied.

Mr. W. KEY (Tradeston, Glasgow): Mr. Smith deserves great credit for this setting. He has taken a decided step in advance; and those who alter their settings to save labour and wages and fuel do great good to the gas profession. This is a simple arrangement; and it speaks volumes for Mr. Smith's ability that he has to draw his clinker only once in 24 hours, while keeping up a good heat.

The PRESIDENT: I gladly join the members who have spoken in thanking Mr. Smith for bringing this subject before us in such an interesting way. No doubt it has cost him much thought and trouble; but he will gain advantages in many respects from the use of this furnace. Perhaps at a future meeting Mr. Smith will favour us with the fuller results of the working of the furnace.

Mr. SMITH: Mr. Young has kindly answered one of the questions in regard to the length of time which elapses between the cleaning of the fires. We generally clean the fire every day except Sunday. The clinkering at first caused us some difficulty; but since we began to use spent shale, clinkering, in the sense of clinkering, has not had to be resorted to for three months. If we just touch the clinkers, they loosen without difficulty, and the stuff falls away.

The PRESIDENT: You speak of not clinkering on Sundays. Do you work the retorts on Sundays?

Mr. SMITH: There is not much difference in the quantity of fuel used on Sundays as compared with other days.

Mr. KEY: Will Mr. Smith inform us how he gets the clinker off his furnace-bars, where the primary air comes into contact with the fuel?

Mr. SMITH: We never try to take the clinkers off there. There is a quantity of black ash at the bottom; but there is nothing spread on the bottom to make clinkers. Whatever clinkers there may be are on the top, where we can easily get at them.

MR. KEY'S PAPER.

Mr. W. KEY (Tradeston, Glasgow) read the last paper, which was on "The Scrubbing, Condensing, and Washing of Coal Gas," and has already appeared (*ante*, p. 290). After reading his paper, the author experimented with crude oil, to show how its contact with gas deteriorates the illuminating power. He explained that when he made the experiment with oil at a low heat, the effect was to put out the gas; and he accounted for the failure of his experiments in the presence of the members by stating that the oil was at too high a temperature.

Discussion.

Mr. J. DONALDSON (Lochwinnoch): I think the thanks of the members are due to Mr. Key for his able paper, dealing as it does with an entirely new departure in gas manufacture. I consider that the plan of taking the tar from the gas before it enters the condensers is a valuable one, and that a very great saving will be effected by so doing. It should recommend itself to all gas managers. As Mr. Key would have shown by his experiment, the illuminating power of gas is depreciated by coming in contact with cold oil; and by his arrangement this would be much reduced, and the gas kept up to the standard illuminating power with a much less quantity of rich coal. This is no new idea of Mr. Key's, as he mentioned it to me more than a year ago.

Mr. P. WATSON (Stirling): Is this a patent?

Mr. KEY: No.

Mr. WATSON: Is it working anywhere?

Mr. KEY: It has only been working on the small model I have shown you.

Mr. A. MACPHERSON (Kirkcaldy): We are obliged to Mr. Key for his excellent paper, and for the exceptionally fine diagrams with which he has illustrated his remarks. I have had a notion for a long time that it is wise to separate the hot gas from the tar as soon as possible, and not allow them to travel together, as the illuminating power is thereby deteriorated. Mr. Key's proposal, therefore, is nothing new. In regard to the scrubbing arrangement, I think it is a good one. I do not mean to say that Mr. Key's apparatus is the best that could be adopted; it is the

principle I am speaking of. Some years ago, when Mr. Miller, of Innerleithen, brought the subject before us, he worked on the same principle. He had converted a large disused tank into a sort of settling-pit, where the gas was allowed to separate, and the tar to drop. I have no doubt this "whisking" of the gas will have the effect he says the machine will have, of extracting a large proportion of the tarry particles from the gas before it passes on. Then in regard to the condenser, there is no doubt that if he keeps his condenser pipes clean by extracting the tar, he will have far more effective working from his condenser than if it were to become coated inside with tar. The condensing of gas is a thing that does not receive sufficient attention. The condensing apparatus ought to be thoroughly under the control of the manager of the works. I can maintain my illuminating power by watching the temperature at which the gas is being discharged at the outlet of the condenser. In this respect, Mr. Key is bringing forward a principle which is well known to us, but which is perhaps not acted upon so fully as it might be. I know a number of people who would rather have a low temperature at the outlet of the condenser, at the expense of the illuminating power, than measure the gas hot. An apparently large leakage account is no loss, but a profit. By reducing the temperature of the gas to perhaps 30° or 40°, we effect a saving on the register of the station-meter, but at the cost of the illuminating power of the gas; so that it is really no saving at all. Though you have a higher leakage account, it may not be a loss but a gain. The temperature at which the gas is discharged from the condenser is, I consider, a most important element. In regard to the scrubbing arrangement, I am not quite sure that it will be effectual. There will be a certain amount of tarry matter carried forward; and I am afraid the corrugated sheets will become clogged up. Mr. Key's apparatus reminds me of Mr. Whimster's washer turned upside down, or that of Mr. Reid, of Leith. It is a little varied in construction, but the principle is the same. There is no doubt that, in purifying gas, intimacy of contact between the washing material and the gas is the main thing before we can hope to accomplish the object at which we aim. If this is effectual, and gives us intimate contact, the machine will be successful. In regard to the failure of Mr. Key's experiment, I do not see how he could expect to have success, because he tells us he took the oil from the inside of the gasholder. Instead of reducing the illuminating power, I think he should increase it. Of course, if you put in oil from an oil-works it will be different. I know nothing worse for reducing the illuminating power than a fine naphtha tar in the bottom of the washer.

Mr. G. R. HISLOP (Paisley): With a great deal of what Mr. Key has said I agree; but there are various opinions entertained on some of the points he has brought under discussion. There is no doubt that this is a new feature in washing gas. In my opinion, it matters little where you get rid of the solid particles, if you do get rid of them. There is no doubt of the damaging effect of some condensers on the illuminating power of the gas; and for this reason we have long ceased to put up condensers in the old form. We have pipe condensers; but they are different from what is known as the ordinary pipe condenser. The pipes are set in rows, and closed in a tank at top and bottom; and as they are made exactly level, the water runs down the pipes, and they are kept as clean as if they had been washed with a brush. That is the form of condenser I have adhered to for a long time. I agree with Mr. Key as to the effects of tarry matter in the other form of condenser, and therefore I have discontinued its use. I make it a point to have the temperature of the gas carefully examined. It will be found to be a great advantage to maintain the temperature as high as possible, even at the risk of losing a large quantity of ammonia. The benefit of maintaining a high heat is great, because the hydrocarbons are deposited in the main, and they are largely lifted up again and carried away. What is deposited in the colder weather is immediately taken up again. It is important to keep the temperature as high as possible, consistent with taking the impurities out of the gas on its way to the station meter. I aim at keeping it at 55° in winter; and it is a rare occurrence if it goes down to 50°. From the time the gas leaves the condenser until it gets to the end of the scrubber, I lose perhaps 15°; so that were I to take observations at the end of the condenser, my gas would be seriously deteriorated before it reached the end of the scrubber.

Mr. J. M'CRAE (Dundee): The first thing that occurs to me is that we ought to be indebted to Mr. Key for the manner in which he has brought this subject before us; but although we may admire his diagrams, that is no reason why we should adopt his theory without examination. I ask what benefits are to be derived from adopting this process. Has it been worked in any place? Is it not a fact that this corrugated iron will be seriously affected by the foul gas passing along? Will this corrugated iron not be filled up, so that you will have two smooth surfaces rubbing together? In regard to the placing of the scrubber before the condenser, it is like putting the cart before the horse. We have all learned that the gas should be gradually lowered in temperature, and that the temperature should be noted at certain points with care and regularity. I presume this is done in all well-managed gas-works. Mr. Key censured the adoption of annular condensers. I do not see the force of that. In my opinion, there is no part of the process of gas manufacture so little known to the gas engineer as the effect of condensers on the heavy hydrocarbons contained in coal gas; and I question whether we, after leaving this hall, shall be very much further enlightened by what we have heard. He has been severe on annular condensers. As an engineer who has erected annular condensers this falls heavy.

What is the meaning of a condenser? Do you not depend upon the weather; and must not the condenser be affected by the temperature prevailing at the moment? It is quite true that in winter you must use means to check excessive condensation. This is done in all well-regulated works. The temperature is taken into account; and the moment you go below 70°, you close the sluices of the internal pipes of the annular condensers, and thereby the condensing power is reduced, and the gas kept at an equal quality. I should like to know the cost of this apparatus as compared with the annular condenser, and also to be informed what is to be gained by using it. We should know how far, and to what extent, the various temperatures affect the illuminating power of the gas. A very important difference exists here, and it is not commonly known; but it is well that it should be understood. For example, if you, with a certain mixture of coal, supply 26½-candle gas in the summer time, what quality of coal would you require to use to supply a similar quality of gas in the winter time? This is a point which many have overlooked; and it demands much consideration. It is well known that excessive temperature, either high or low, has a decided effect on coal gas; and the question ought to be suggested for solution to some gas manager who has the means of ascertaining what that effect is. Some years ago, another Gas Association took up this question; but I do not know that very much good came of their investigation. I think some definite results might be arrived at, and information obtained which would be important to us all.

Mr. A. SMITH (Aberdeen): It should be borne in mind that there are a great number of annular condensers being erected; and unless Mr. Key has something definite on which to condemn these appliances, I do not think he should have brought the subject so prominently forward. The annular condensers occupy much less space than the pipe condensers; and you have the same power over the one as over the other. I think a number of condensers should be thrown out of use during the cold weather. From the discussion of this paper, I do not consider we should run away with the idea that there is no condenser right, but the one adopted by Mr. Hislop. That would be most absurd. Mr. Key's diagrams of his scrubbers are very beautiful. But I am a good deal of the opinion of Mr. McCrae, that you must have means for washing them out; and my experience is that the simpler you can make apparatus for gas manufacture and purification the better. To my mind, Mr. Key is, in this respect, taking a step in the wrong direction. I am not so sure that driving the gas at the rate of 300 revolutions a minute is calculated to improve it. If this is found to be good, a jet of steam would clean the corrugations. Although I cannot agree with Mr. Key, I thank him for bringing forward this subject.

Mr. HISLOP: I hope Mr. Smith will not go away with the idea that I hold that there is nothing in creation like the condensers I have. I simply stated what I had adopted in preference to other kinds. Many of these things are merely matter of opinion; and I simply put forward my ideas on the subject.

Mr. MACPHERSON: Mr. Smith included me as one of the condemners of annular condensers. I did not condemn them, because I think that properly constructed annular condensers can be as well controlled as any others.

Mr. S. STEWART (Greenock): I quite approve of what Mr. McCrae and Mr. Smith have stated in reference to the use of annular condensers.

Mr. KEY: The object of my paper was to raise a discussion; and I am pleased with what has taken place, because it was for the purpose of obtaining an improved method of conducting our business that the paper was prepared. Mr. MacPherson agrees with me as to the temperature to be maintained throughout the apparatus; but when he comes to the washer, he expresses the fear that it will become clogged. That is an utter impossibility, as the water and the clean gas can never clog up the corrugations by this arrangement.

Mr. MACPHERSON: We have had examples of clogging in other things.

Mr. KEY: At 60° it is an impossibility; but if you go down to freezing point, you will have naphthalene. As to the form of the washer, Mr. MacPherson says it reminds him of Mr. Whimster's or Mr. Reid's; but they are not at all alike. The principle of Mr. Whimster's is a system of boxes; and Mr. Reid's is a long vessel with a revolving cylinder, and having a number of trays lifting up water, which percolates through to the gas. I say that it is spray that is wanted, and not drops of water. Anyone looking at it will see that there is no resemblance to either Mr. Whimster's or Mr. Reid's plan. Mr. MacPherson thinks the oil may be expected to enlarge the flame of the gas; but I am perfectly certain that, when at a low temperature, the oil will depreciate the gas 50, 60, or 80 per cent. I shall keep some of this oil for the purpose of making further experiments; and perhaps you may hear of it again. Mr. Hislop seems to think it does not matter how or where we get rid of the tarry particles, so long as we do get rid of them; but I hold that we should remove all the tarry matter from the gas before we pass it into the condensers. I propose to take it out before it enters the condensers, leaving the coolers and condensers to do their own work. Mr. Hislop agrees with me about the annular condensers. Others may have different methods of arriving at their conclusions. I have noticed the thermometer inside an annular chamber go up when the sun rose; and I have seen it go down 20° in five minutes in a shower of rain. The condenser I recommend is something we can go by—something we can regulate by the movement of a lever. Mr. Hislop also

agrees with me about maintaining the heat, and as to the loss of temperature between the condensers and the scrubbers. He has told us it often loses 15°—just what I stated in my paper. Mr. McCrae has asked what benefit will be derived from this arrangement. I cannot give the benefit in pounds, shillings, and pence; but I have formed a very good opinion of the loss sustained under the present system. I say that at least 10 per cent. of the value of your coal will be saved every day during winter by this arrangement. What other benefits will be derived can only be found out when the system is put into operation. As to the choking of the corrugations, I say it cannot be, because, with gas passing in at from 120° to 160°, such a thing as any solid matter being there is an impossibility. The liquor I obtained at the outlet was very liquid indeed.

The PRESIDENT: While thanking Mr. Key for his paper, I must say that it would have been of much more value had he given us some practical results. A pound of theory has been in vogue; but what we want is the ounce of fact. If he had put the apparatus to the test, and given us some facts after he had had it in use, it would have been much better for us all. He has spoken of having had it "in pickle" for a number of years. It would certainly have been better if he had put it in operation. We have for some months been working with an apparatus at Dawsholm, but do not mean to say anything about it until we are able to state something definite. It was premature on the part of Mr. Key to give us only theories; he should have waited until he could show us actual results. The 10 per cent. saving of coal on which he reckons is merely a matter of assertion. It is easy enough to say such a thing; but if there is nothing to support it, it would have been far better if it had never been said. We have now come to the end of the list of subjects for discussion; and I ask you to accord a hearty vote of thanks to the readers of the various papers. They have added very much to the success of the meeting; and I think we shall go away much the better for all we have seen and heard.

THE PRESIDENT'S MEDAL.

Mr. J. McCRAE (Dundee) said that there were two very pleasant features characteristic of the Scotch gathering of gas managers. In the first place, the meeting was always agreeable; and, in the second place, its end was always pleasant. They had come to the close of one of the best meetings the Association had ever held; and a very pleasing duty had fallen on his shoulders, to present Mr. Terrace with the highest honour the Association could confer on him—viz., the presidential gold medal. It was not alone the intrinsic value of the medal, but it was something to hand down to one's children, to show the estimation in which he was held by his brethren in the craft; and he was sure no one who had preceded Mr. Terrace had more worthily earned the distinction than their present President. With these remarks, he asked Mr. Terrace's acceptance of the medal, assuring him that every member of the Association, absent as well as present, wished him many years of happiness and prosperity.

The PRESIDENT thanked the members for their great kindness in awarding him the medal, and Mr. McCrae for the happy manner in which he had expressed their sentiments in making the presentation.

VOTE OF THANKS TO THE SECRETARY.

Mr. HISLOP said the meeting should not be allowed to break up without remembering one gentleman who had done so much to ensure its success—viz., the Secretary; and he had great pleasure in moving a hearty vote of thanks to him for the energy and ability he had displayed in conducting the affairs of the Association.

The proposition was carried with applause.

Mr. CARLOW, in returning thanks, said it had been a great pleasure for him to be their Secretary during the past year; and if he had done anything to further the business of the Association, and make the meeting a success, he was amply repaid by seeing so large a gathering of the members.

This concluded the business of the meeting.

In the evening the members and their friends dined together in the Royal Bungalow of the Exhibition—Mr. Terrace presiding. After dinner some time was spent in viewing the exhibits. The following day an excursion was made from Glasgow to Lech Lomond and Loch Long; a pleasant day being spent.

In his report on the technological examinations of the City and Guilds of London Institute for the present year, Sir Philip Magnus (the Organizing Director) says that there has again been a large increase in the total number of candidates. In 1887, 5508 were examined, of whom 3090 passed; in 1888, 6166 were examined, of whom 3510 passed. The increase in the number of candidates is 86 less this year than last. Examinations have been held this year in 49 different subjects, in seven of which less than ten candidates presented themselves. The subjects in which the least number of candidates came up are those connected with the chemical industries; and the Examiners in these subjects generally remark that few of the candidates are found to possess that combined knowledge of scientific principles and of technical processes which is desirable. The average percentage of failures has fallen from 43·8 to 43·1; and from the separate reports of the Examiners it appears that in most subjects there is a distinct improvement in the quality of the candidates' written answers and practical work. Of the 3510 successful candidates, 758, or 21·6 per cent., have passed in the Honours grade, as against 21·9 per cent. last year.

NORTH OF IRELAND ASSOCIATION OF GAS MANAGERS.

THE PAPERS READ AT THE ANNUAL MEETING AT LISBURN.

In the JOURNAL last week we published a general report of the proceedings at the first annual meeting of the above-named Association, held at Lisburn on the 14th inst., with the Inaugural Address delivered by the President (Mr. E. Stears). We give to-day the three papers read, with the discussions which took place thereon.

Mr. W. R. FEATHERSTONE (Dundalk) read the first paper, entitled—

THE UTILIZATION OF TAR AT DUNDALK.

The low prices offered for tar at Dundalk caused me to use up all my surplus; and, after 18 months' experience, I estimate the value of our tar to be at least 30s. per ton. We have no steam power to spray the tar, yet for weeks no coke was consumed; tar taking its place in the furnaces.

The following extracts from our annual statements of accounts prove the value of tar:—

Cash received by Sales each Year ending June.

	1885-6	1886-7	1887-8
	£ s. d.	£ s. d.	£ s. d.
Coke	553 5 2	603 14 4	795 10 5
Tar	104 0 4	91 15 8	150 5 1
Liquor	28 3 9	35 16 4	51 11 5
	£685 9 3	£731 6 4	£997 6 11
Coal carbonized	2943	2776	2764
	Tons.	Tons.	Tons.
Coke sold without tar burning in 1887			670
Do. with do. in 1888			1015

Increased coke sales in one year = 345

The surplus tar was used in various ways. It was employed for firing retorts; for roadways and footpaths; for the gasholders, in lieu of paint; for mixing with fire-clay, to repair the furnaces, retorts, &c.; and for stopping leaks in the gasholder tank.

In making tar concrete, the material—cinders, stone riddlings, gravel, &c.—should be first drenched with water, and regularly puddled. Then add 1 gallon of tar to 3 bushels of material, and thoroughly mix into a slush. Do not heat either stuff or tar. This mixture can be laid at any time in dry weather. For the retort-house, a flooring of tar concrete is hard and clean. It stands heat, rough carts and horses, tipping coals, with the usual turning, backing, &c. After twelve months, it is a decided improvement over the stone paving it replaced, as one man can run 5 cwt. of coal in a handcart with less trouble than 2 cwt. with the old paving. The main flue does not affect it, running underneath. To lay concrete, first get a good foundation by levelling and rolling. Spread the mixture, drench it with water, and roll and pour on water until both tar and water issues out in streams, and a skin forms on the surface. Leave it to dry; then coat it well with boiling tar and 1 pint of paraffin oil to a gallon of tar—about 1 gallon of tar and oil to 5 square yards; then dust it over with sand, and in ordinary summer weather it will rapidly dry, set, and become waterproof. This can be thoroughly well done for from 9d. to 1s. per square yard. For tarring the gasholder, I first scraped off all the old paint, and then coated it thinly with hot tar, thinned with paraffin oil.

To ascertain the daily stock of tar in the yard tank, an old meter-case forms a float, weighted to sink in liquor but float in tar. A staff with a pointer indicates the height of the tar; and, with very little assistance, the float can be raised to the top of the liquor, and thus determine the depth of both tar and liquor separately.

I do not consider it advisable to burn tar closer than 2 feet, or even 2 ft. 6 in., from the point of ignition to the bottom of the retorts, without protection. I make the tar-burner to swing out of the way like an ordinary bracket; and find brass or lead nipples better than iron.

In using tar for firing, I employ the arrangement shown in the drawing. The tar is lifted direct from the yard store-tank by an ordinary force-pump fixed against the wall outside the retort-house, into tanks placed upon the retort-beds, two tanks to a bed, connected direct by 1½-inch pipes along the top of the bed. The tar is supplied to the burners by a ¾-inch service-pipe, taken from the bottom of the tank A. This pipe descends to within 2 feet of the retort-house floor; then rises where a screen is fixed, and runs

along the front of the mouthpieces to a similar screen. But the pipe enters the tank B 12 or 15 inches higher up. Along the front, tees (plugged up) are fixed, to screw on a bracket as required. The advantages of this arrangement are that the tanks can be easily emptied, vapour does not form in the pipes and cause a bad flow, but a circulation is formed; and when the tar is low, the vapours do not block the pipe. The screens cleaning the rising tar do not clog; and the flow can be reversed, and screened tar used to clean its own screen—any sediment being run off at the tap.

The furnaces consume coke only when it cannot be sold, or when the tar is low in the tank. A lump is made with two tiles, banded and packed wedge-shape; and into these grooves are cut for a

1½-inch wrought-iron pipe, opened at the end to receive the tar. They are let into the wall over the furnace-door when a coke fire is converted. A coke fire can be turned into a tar-burning fire without any stoppage.

Discussion.

The HONORARY SECRETARY (Mr. J. Whimster, of Armagh) said he was very glad to have heard Mr. Featherstone's paper, which was upon a subject of the deepest importance to every member of the Association. It was a great thing, in his opinion, to have the means of utilizing tar satisfactorily; and it seemed to him Mr. Featherstone had been very successful in his work. With reference to the portion of the paper which dealt with the use of tar for the making of roads, he was very much surprised at the idea of drenching it with water. He had hitherto believed that it was necessary, for the successful employment of tar in this way, that it should be kept as dry as possible; but he now saw his mistake. He thought this idea of Mr. Featherstone's a very useful one. Again, with reference to the burning of tar, Mr. Featherstone's description of the system he adopted was most interesting; and he (Mr. Whimster) was sure the author had hit upon the right thing in that respect. It was a most reasonable and sensible one, and had in Mr. Featherstone's hands worked with most satisfactory results. He was very glad to have had the opportunity of hearing so practical a paper on such a subject; and he was sure the information it contained would be useful to them all.

Mr. J. GIBB (Newry) desired, with the Secretary, to express the pleasure it had given him to hear Mr. Featherstone's paper, which contained a great deal of information that would prove useful to them. The subject was, as Mr. Whimster had stated, one of the very greatest importance to them, because they could get little or nothing for their tar; and it was of the utmost importance to them that they should have a satisfactory mode of utilizing it. The arrangement which Mr. Featherstone had described to the meeting was an excellent one; and the author had introduced several things of which he (Mr. Gibb) had no idea. The arrangement by which Mr. Featherstone had obtained complete circulation of the tar was certainly ingenious, and overcame several great difficulties. He wished to express his appreciation of the valuable hints the paper contained, and which he thought might be taken advantage of by them all with profit. There was one point, however, which he did not catch very clearly when listening to the reading of the paper, and upon which he would be glad of a little more information, and that was exactly how far the pipe from which the tar issued was allowed to project into the air.

Mr. FEATHERSTONE said he had already fully explained in his paper how the tar was introduced into the furnace; but he might say further, in reply to Mr. Gibb's question, that the pipe conveying the tar was put just so far into the furnace that the tar, on issuing from the end of the pipe, dropped right into the middle of the fire.

Mr. GIBB said he had another question which he would like to have answered, and that was with regard to the smoke resulting from the burning of the tar. He wished to have some information as to the arrangement by which Mr. Featherstone got rid of the smoke, as he did not deal with this matter in his paper.

Mr. FEATHERSTONE replied that the tar burned with a white flame; and there was no smoke from it. Consequently, there was no smoke to get rid of.

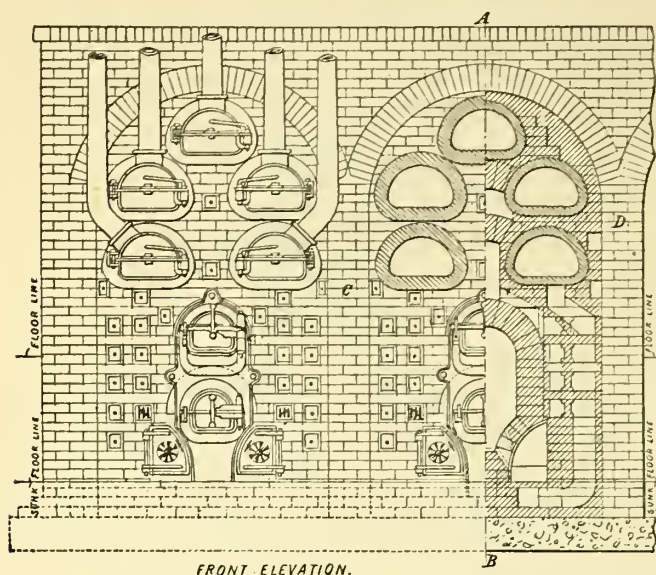

The PRESIDENT remarked that the fact that there was no smoke showed that the tar was being consumed.

Mr. FEATHERSTONE said this was perfectly correct. If the fires were all right, the tar was completely consumed; and therefore there was no smoke. It was necessary, however, in order to obtain the complete combustion of the tar, that the fire should be kept up to the proper heat; and the tar burned so brilliantly in the furnace that at night it looked like a star.

The PRESIDENT said they were all much obliged to Mr. Featherstone for his paper, and also for having answered the questions put to him.

Mr. A. WADDELL (Newtownards) next read the following paper:— EXPERIENCE WITH MR. G. R. HISLOP'S REGENERATIVE FURNACES.

The regenerative system of heating has, up to the present, received very little attention from gas managers in this country. Indeed, one would think from the results claimed for it by English and Scotch managers who have adopted it, that it would long ere this have obtained a footing on this side of the Channel. But perhaps, we are all too slow to move out of the old ruts of ordinary routine, and adopt the newer methods which the more daring or

more speculative spirits have attempted, and in some instances with marked success. It may be that we are all too conservative of what has the stamp of approbation from those who have made gas so successful as an illuminant in the past, and fear to differ from them or cast a reflection on their judgment. Others perhaps may have been deterred from giving the system a trial, lest the cost should exceed the profit; or they may have had serious doubts as to the genuineness of the claims put forward on its behalf. Be that as it may, I think I am safe in saying that the system has not been adopted yet in any part of Ireland, except in Newtownards; and therefore I consented the more readily to give you the result of my limited experience.

Whatever system can show the most favourable results on the year's operations must, of necessity, carry the day. Gas has now two very powerful opponents, each competing for a share of the patronage of the public—electricity and oil. The latter is a very powerful opponent, because of its cheapness; the other, because of its brilliance. Therefore gas, to hold its own, must be produced at the lowest possible price; and, in order to do so, the gas manager must be keeping his eyes open to every improvement which promises a saving of expense or an increase of production. I do not know that I can serve the North of Ireland Association of Gas Managers better than by simply telling them what I have done, and with what results.

At the beginning of November last, I had completed the work of taking down two old ovens containing four retorts each, and replacing them by two new ovens with settings of five retorts, heated by Mr. G. R. Hislop's gas producers and regenerators. During the last few years the regenerative system of firing has formed the subject of many instructive and interesting papers read before Gas Associations; and I think you will agree with me that the conclusions to be drawn from them, and the discussions which followed, are that to obtain a uniform heat throughout a setting, combustion must take place not at one part, but along the whole length of the oven, and that it is desirable to take as much heat from the waste gases as economy will allow. Few managers even of large works care to adopt elaborate and consequently expensive regenerators; while managers of small works find the cost absolutely prohibitive. The conclusion, therefore, is in favour of the shallow-chamber principle, such as forms the subject of this paper.

I will endeavour to describe to you, with the assistance of the diagrams, Mr. Hislop's system, so that you may judge how far it meets your approval or otherwise. The producer is 3 ft. 6 in. high, 1 ft. 9 in. wide, the bottom 3 ft. 6 in. in length, formed by arches as shown, being supported and kept air-tight by cast-iron plates, each having three port-holes through which primary air passes, after being adjusted (as desired) by discs in air-tight doors. Underneath these port-holes a pan containing water is placed, which has part of the waste gases carried under it, so as to

evaporate steam in order to soften any clinker that might form, or to keep it from forming. This saves the expense of raising steam and laying down steam pipes, and only requires a water pipe introduced on the top of the triangular door frames, from which the water drops into the ash pans. The top or arch of the producer is continued the full length of the oven, having port-holes in the centre, through which the producer gases pass into the combustion chamber, and meet the secondary air supply, which has been heated by travelling along flues situated between the producer and the waste gas flues; passing finally by port-holes into the combustion chamber directly opposite the gas producer port-holes—causing the gases to mix well. The sides of the combustion chamber are formed by the same wall that protects the sides of the bottom retorts, on which arches rest; leaving port-holes equal in area to one-half the top of the chamber, from which the gases travel over and around the retorts and underneath the bottom retorts to the waste-gas flues, heating the secondary air, &c., and thence to the chimney. There is not in the whole building one specially-made brick. The setting is easily built; and every one of the flues can be readily got at if they require cleaning. But this I have had no need to do; the whole setting being quite clean after a season's work.

Some of the advantages of this over the old or direct system of firing, are regularity of heat in the retorts, and greater control over the heat when stopped working, obtained by shutting the dampers and discs. One fire will then last ten or twelve hours; and even then there is heat sufficient to burn off a moderate charge in four hours. This is a great advantage where there is a desire to do away Sunday labour, or in small works where in summer enough gas is made in 12 hours to serve for 24 hours.

In adverting to the results, I may say that we have been able to make at the rate of 8000 cubic feet of gas per mouthpiece every 24 hours—an increase of 60 per cent. as compared with the old system of firing; for then it was difficult to maintain a make of 5000 cubic feet per mouthpiece every 24 hours. We charge the retorts every four hours; fill the producer every three hours; and clean the same once every 12, and sometimes once every 24 hours. But as this means only the drawing of ash or soft clinker from the bottom door by a rake, and dropping the contents of the producer (meanwhile held up by a thin arch of clinker, preventing the cold air from entering the oven during the process), this seldom takes more than two or three minutes. The saving of labour is thus very considerable. Judging from the condition of the retorts as they now are, I have good reason to believe that they will last one-half longer than when built in an oven heated by a direct fire. The appearance of the producer and regenerators also justifies me in saying that they will last at least two, if not three, settings of retorts. During the same time, if working with common furnaces, it would have been necessary to rebuild and repair them a dozen times; so that, although the common furnace is much cheaper at

first, the expense of rebuilding and repairing it for say six years, would make it nearly as expensive per annum without any of the important advantages.

Since introducing this system of heating, we have made 560 cubic feet more gas per ton than formerly, with 30 per cent. of the coke produced; and I have no doubt we shall be able to do better this year. From the beginning, we have had continued satisfaction; and I would not for a moment think of resetting any retorts on the old plan of firing. My opinion is that this system will continue to force itself upon gas engineers and managers until it becomes universal.

Discussion.

Mr. NISBETT (Aughnacloy) observed that he was sure he was expressing the opinion of everyone present when he stated that the paper they had just heard was a most important one, and the subject one that deserved their very best attention. He had listened with great interest to Mr. Waddell's communication; and had profited very much by the account he had given of Mr. Hislop's regenerative furnace. It was to their advantage to give careful consideration to all the most recent improvements in the appliances for the production of gas with the smallest amount of labour and cost.

Mr. WHIMSTER endorsed the remarks of Mr. Nisbett with regard to the interesting character of the paper they had just heard; but, proceeding to discuss the merits of the regenerative furnace, he remarked that, while he looked upon the make per retort as being pretty high, he did not consider that the use of this particular furnace would result in much saving. There was one matter upon which he would like some information, and that was as to how far below the surface Mr. Waddell had to go in the erection of his furnace. He also wished to know how high the furnace was.

Mr. WADDELL said he had to go 3 ft. 6 in. below the surface; and he thought the furnace was about 22 feet high.

Mr. WHIMSTER said there was no doubt that Mr. Waddell, according to the figures he had given them, had attained excellent results, as far as the quantity of gas produced per ton of coal was concerned; but he (Mr. Whimster) could not understand the enormous quantity of coke the author used.

Mr. WADDELL said it was absolutely necessary that the gases should become well mixed; and one of the advantages claimed for the use of the furnace in question was that this was effected. Again, it was most desirable that the mixing should not take place at one point, but all the way round.

Mr. WHIMSTER remarked that this was exactly what could not be done. The gases could not be made to mix all the way round. It would take place the moment they met.

Mr. WADDELL said he was pleased to have had his paper criticized; and he would try to benefit by the criticisms. There were, of course, many things which they would like to be able to do, but they could not succeed; and the only object he had in writing his paper was to give the members of the Association the benefit of the experience he had gained in the use of Mr. Hislop's furnace. With reference to the Honorary Secretary's statement that the percentage of coke used was very high, he (Mr. Waddell) admitted that this was so, but it was part and parcel of his experience; and this being the case, he felt he ought to mention it.

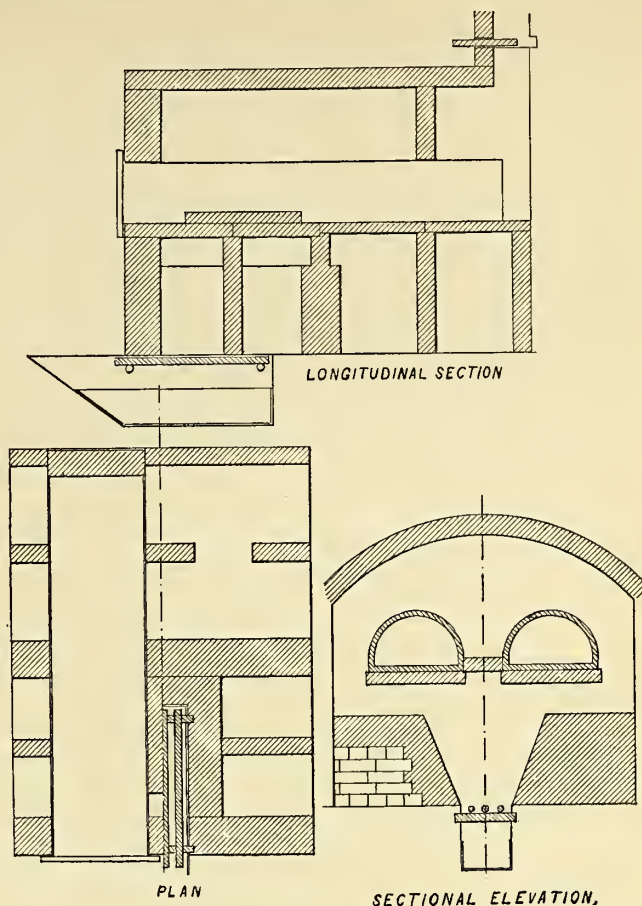

Mr. W. S. STORMONTH (Coleraine) said Mr. Waddell had given the members some very valuable information; and it should also be said that he had stood very good-naturedly the criticism of his paper.

Mr. J. ROBB (Limavady) then read the following paper:—

RETORT-SETTING FOR SMALL GAS-WORKS.

In attempting to lay before you a short account of a system of retort-setting adapted to meet the wants of a great many managers of small gas-works in Ireland, who, like myself, have to struggle against badly constructed works, small consumption during the summer, and very limited funds, I hope those who have more experience in these matters than I have, will deal leniently with any blunders I may make in the literary part of my work.

During the period I have lived in Ireland, I have been surprised at the yield of gas obtained per ton of coal in small works; some returns showing as little as 3000 cubic feet on the consumers meters, while a great many average only 7000 to 8000 cubic feet on the station meters. Now, in looking for the cause of this, I find much of the evil is due to the want of summer consumption. The retorts are kept going all through the summer, and very often only charged once in two days. This style of working swallows up all the coke saved in winter; and then recourse must be had to coal. But why should this be so? Simply because if the heat on the retorts is once let down, it cannot be brought up again in anything less than a week or a fortnight. This may seem strange to some of you; but still it is a fact, and it is not to be wondered at, when we see the class of men who have hitherto had charge of these works. The salaries offered in some cases are not sufficient to procure proper food; and working as they do from six in the morning until twelve and occasionally later at night, there is no time for thought, and no money to spare to acquire knowledge from the experiences of their more favoured brethren. At the same time a lot of useless, nominal officials, have been drawing salaries, sometimes twice and even three times as much as that of the manager. If these salaries were given to the manager, who, with a little labour assistance could do all the work, he, having a little time at his disposal, would be able to improve himself; and, with the aid of an Association like this, the small works in Ireland

would soon bear comparison with those similarly circumstanced in England or in Scotland, and also prove more profitable for both producer and consumer.

Having to meet difficulties in carbonizing of the kind just described, I will simply relate how I got rid of them. When I took charge of the Limavady works about two years ago, out of nine retorts I had none that would work to my satisfaction. During good dry, mild weather, I could get a heat sufficient to yield 9000 cubic feet of gas per ton; but whenever cold wet weather set in, away went my heats, giving a correspondingly low return, of about 8000 cubic feet per ton, and requiring even then an expenditure of fuel equal to 90 per cent. of the coke made. In fact, it was the old story of the furnace white, and the retorts little more than red. The sudden drop in the temperature in wet weather was caused by the bench being built close up to a 14-inch outside wall, and the flues too small. To save the heat lost through the back wall at that time was impossible; but I determined to improve my retort-settings if possible. With a view to carrying out this purpose, I looked over all the styles of retort-settings I could think of, and consulted all the books and journals I could lay my hands on; but I could find very little that seemed just to suit my case. However, I got as much general information as led me to see that, through the smallness of my nostrils and flues, and the want of a proper mixing chamber for the gases, I was losing more than half the heating power of my fuel, as, instead of getting the theoretical 7000 units of heat due to the combustion of coke to carbonic acid, I was only getting in the oven the 2400 units due to its combustion to carbonic oxide. I therefore concluded that the oven ought to have a mixing chamber sufficiently large to allow the complete combustion to carbonic acid to take place before the gases circulated through the setting, and then have such an arrangement of flues as would utilize the gases as much as possible. My idea was to get the greatest heat at the front of the bed, and then by a zigzag course to extract the heat—the one chamber to act as an economizer to the other—and so keep up an equal heat along the retort. To find the capacity of my mixing chamber, I measured the air-spaces of my fire-bars. I have four air-spaces, each 21 inches long by 1 inch broad, which is exactly 84 square inches. The most economical velocity for gases is said to be 60 feet per minute; and my coke-space was 1 foot deep. I then calculated thus: Allowing, for practical purposes, an expansion of 1 cubic foot per degree Fahr. of heat generated for every 500 cubic feet of air entering the fire, and, as air absorbs heat very rapidly and just as rapidly gives it up, assuming that it attains a temperature of 500° Fahr. in its passage through the coke, and that the temperature on complete combustion to carbonic acid is 4500°; then $4500 - 500 = 4000$ cubic feet due to expansion, plus the 500 cubic feet entering = 4500 cubic feet per 500 cubic feet, which is equal to 9 cubic feet per foot of air entering the furnace. But my air entrance was not 1 foot, but 84 square inches; and this, calculated to a velocity of 60 feet per minute, gives 3 cubic feet as the size of the mixing chamber (independent of the coke-bed), which will allow the complete change to carbonic acid to take place.

The next point to be considered was the circulation of the hot gases. To effect this economically, the flues must be neither too

large nor too small; so by simply measuring their length and breadth, and distributing them into 3 cubic feet, and having no part contracted, except at the entrance into the main flue (and that only by the damper), I considered that the oven would be certain to heat up to about the full calculation, and if the flues were evenly divided, an equal heat would be obtained all through. To test this rule practically, I embraced an opportunity which presented itself. I had a double bed of iron retorts, which had not been in use for a number of years, owing to difficulties experienced in getting them to work. Last autumn I took them out, and, finding they were new, reset them in accordance with the principle I have just tried to explain; and, in order to meet the difficulty of the back wall, I built my flues vertically. I divided the oven into three compartments, the first division wall being placed immediately at the end of the furnace bars, and built up the coke bed to a thickness of 14 inches, the remainder $4\frac{1}{2}$ inches, and the second wall $4\frac{1}{2}$ inches all through. The retorts are set only 6 inches apart; and a tile covers this from the first division wall to about 6 inches of the front wall of the oven. The flame from the furnace travels under the bottoms of the retorts, up the sides of the first division, down the sides and under the bottom of the second division, on to the third division, which ascends the same as the first to the damper, which is on the top of the arch, where the waste gases escape into the main flue.

I have now arrived at the most important point in my paper—viz., the practical results. This oven was started on Oct. 1, 1887, and a separate account of the working was kept until March 1, 1888. Owing to my storage being very small, I had to damp down every Sunday, which was somewhat of a disadvantage. The retorts are Δ -shaped, 18 in. by 13 in. by 7 ft. 6 in. long; and the coal used was Arley Mine. There was no exhaustor; and the back pressure was 6 inches. From date to date, they carbonized 130 tons of coal, giving 1,298,300 cubic feet of gas; being 9980 cubic feet per ton. The largest yield of gas obtained in 24 hours was on Dec. 18—being 13,900 cubic feet; and the average make was 6000 cubic feet per mouthpiece per 24 hours. They returned in coke 4700 bushels, out of which we sold 2300 bushels. This shows 50 per cent. of the coke made used as fuel; but the same furnace would have heated six retorts. Our revenue from this source was increased about 200 per cent. Another important matter is that the furnace heats up to carbonizing point in twelve hours, if standing over for a lengthened period; and if from Saturday evening till about ten o'clock on Sunday night, four hours will bring it up to carbonizing heat. There is no difficulty in getting up the heat; on the contrary, we had to use very great caution, and damp down for half an hour at the end of every three hours before charging. After all, one of the sides melted; but, thanks to the use of Sellars's cement, when it had been repaired it was as good as ever.

After seeing the success of this setting, I erected a single bed of retorts on the same principle, following the same rule, and was rewarded with like success. Of course, the saving in coke is not the same, as I have often to damp down for three and four days together; but what I save when working (which is about 15 per cent.) restarts the oven. I am erecting a bed of three fire-clay retorts on the same principle; so I shall learn the adaptability of the rule to them also.

I hope this simple effort to help my brethren in small works will meet with their approval, and that we, in Ireland, may soon be able to stand comparison with similar works across the water. Seeing that the majority of the works in Ireland make from 1 to 3 million cubic feet of gas per annum, I hope it will also awaken a desire in all the members of this Association to aid them.

Mr. A. WADDELL (Newtownards) thought the Association were deeply indebted to Mr. Robb for his paper, which was upon a subject of very great importance to those who were connected with small gas-works. Mr. Robb had dealt with his subject in an able manner, and had made some very outspoken and appropriate remarks upon several points. There were some matters in the discussion of which a little plain speaking was necessary; and he thought Mr. Robb had complied with this requirement. He (Mr. Waddell) only regretted that there were not more like him.

The reading of papers then concluded. The subsequent proceedings were reported last week.

Register of Patents.

GAS MOTORS.—Hahn, E. J., of Frankfort-on-the-Maine. No. 10,176; July 20, 1887. [11d.]

This invention in gas motors is applicable to both rotary and reciprocating engines, and comprises arrangements for admitting and distributing the fluids and gaseous mixture and for igniting the latter.

In a rotary gas motor constructed with these improvements, the piston is fixedly connected with a narrow central disc with boss on the shaft. The latter is to a great extent relieved from the pressure in the cylinder by means of a hollow circular chamber formed at each side of the central disc. One chamber is in one with the back wall of the cylinder, and the other is a loose part which has its bearing in the front wall of the cylinder, and, by means of the cylinder cover and an intervening spring washer, is pressed against the central disc, causing a tight joint to be made against both sides of it. The bulk of the pressure of the explosion, which would otherwise come upon the shaft, comes thus on the chambers, and the force on the front and back walls of the cylinder; while the small remaining portion only comes on the narrow disc, and

thence on to the shaft. The piston-shaped ignition-slide is worked from an eccentric cam on the shaft of the motor; a spring bringing the piston-slide down again. The valve for the inlet of the gas from the producer or carburetter (by preference arranged on the engine) is similarly worked from an eccentric cam on the opposite end of the shaft by means of a double-armed lever; a helical spring serving for raising and closing it. The air-pump for supplying the producer is worked by a crank-pin on the first-named eccentric cam. The pressure in the producer on the engine is kept constant by means of a yielding spiral spring; while the pump delivery-pipe is fitted with a back-pressure valve which closes during the suction.

GAS OR OTHER HYDROCARBON MOTORS.—Wordsworth, C. T., of Manchester. No. 11,466; Aug. 23, 1887. [8d.]

This invention (relating to improvements in gas or liquid hydrocarbon motors, parts of which are applicable to various types of liquid hydrocarbon motors) has for its object, firstly, to overcome the back pressure hitherto experienced in such motors; and, secondly, to provide means for admitting the gas or liquid hydrocarbon in suitable quantities for the purpose of increasing the efficiency of the motor.

GAS-BURNERS.—Walker, C. M., of Dulwich, Surrey. No. 12,952; Sept. 24, 1887. [6d.]

The patentee's proposal is to construct a circular burner in the form of a double socket, having a solid division about midway, so as to form an upper and lower chamber; the gas supply being led into either as may be desired. Both chambers are provided with holes or slits, varying in number, size, and proportion according to the size of the burner. One chamber is for gas, the other for air; the socket burner being fitted, one end to the gas supply, and the other in communication with the

air supply. In the illustrations, fig. 1 is the form of burner used in an ordinary regenerative suspension lamp, in which case A is the gas supply and B the air-way leading to the outside of the lamp. D is a solid partition. Where the gas is led upwards (as upon brackets, chandeliers, harp lights, tees, or other forms), the arrangement is as fig. 2, in which the gas is led up the pipe D (which screws into the gas-fitting at that point) to the burner. The upper part is plugged at C; surrounding D is an air-pipe E, with the base pierced with holes to admit air. To adapt the burner to regenerative lamps having no opening to the external air at the bottom, it is made as in fig. 3; the air-supply pipe F being led into the regenerator and left open at the top. H is the air chamber; G being the gas-box connected by two or more passages to the gas supply at J.

REDUCTION IN PRICE.—The Bingley Improvement Commissioners last Tuesday announced that, as from the 22nd of June last, the price of their gas is reduced to 3s. per 1000 cubic feet, subject to discounts of 15, 17, and 20 per cent. on accounts up to £100, £150, and £200, provided they are paid within three months from the close of the half year to which they refer.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

MR. MACPHERSON'S REMARKS ON GAS-BURNERS AT THE NORTH BRITISH MEETING.

SIR,—In the "Editorial Notes" in your issue of the 21st inst., I notice you draw attention to a "term" used by Mr. MacPherson, and proceed to read me and others a lecture on the loose use of the word "regenerative." In looking over the report of the discussion on Mr. Hislop's paper, I find I am reported to have said: "I believe, from experiments, that a large chamber just below the point of combustion acts on the regenerative principle." Now, as I never made any such absurd statement, the "term" said to have been used by me must be credited to someone else—who, I do not know.

If you turn back to the discussion on the paper read by Mr. Wm. McCrae at our meeting in Stirling last year, you will find, from my remarks there, that I am as able to discriminate between what is and what is not regeneration, and am as anxious that the word should not be used loosely, as you are. Consequently, I think you must be indebted to your reporter for affording you the opportunity of making the necessary correction, "in the interest of precision of knowledge and expression." When, however, you were in your instructive mood, why did you not, "in the interest of precision of knowledge," draw attention to another reputed statement of mine, which occurs in your report, nine lines further down, that the "oxygen that passes through is given off as soot"—certainly as ridiculous a statement as the other, which I must, also, I am afraid credit to your reporter? Surely when you noticed the one, you might at least have given me the honour of an editorial notice of the other as well, unless, of course, you consider this latter to be in accordance with "the precision of knowledge."

I would not have troubled you with any correction of your report, however absurd and nonsensical, had it not been that I have thereby been raised to the dignity of an editorial notice on false pretences, which honour I must modestly disclaim any right to, as I did not use the "term" which has afforded the necessary opportunity of doing so.

A. MACPHERSON.

Kirkcaldy, Aug. 24, 1888.

[With regard to the matters mentioned in the above letter, we have only to say that the report of the proceedings at the North British meeting, of the correctness of which complaint is made, was supplied by the reporter engaged by the Association; and that the words which Mr. MacPherson denies having used are in the transcript of the reporter's notes as approved and passed for publication by the Revision Committee of the Association.—ED. J. G. L.]

READING GAS COMPANY.—In the report to be presented to the shareholders of the Reading Gas Company at their half-yearly general meeting to-day, the Directors state that the necessary plant has been placed in the new works, of which a description was given in the JOURNAL for the 14th inst., and the manufacture of gas for the supply of the Company's district is, for the present, carried on exclusively therein. The erection of the buildings, and fitting them with apparatus on the regenerative principle, has been a work of the greatest anxiety to the Engineer and to the Directors; but it has been carried to a most successful issue by their Engineer, Mr. E. Baker, Assoc. M. Inst. C.E. The works were brought into operation in the spring (as anticipated), and were found to answer all the expectations formed of them; and the Directors confidently hope that the result will be eminently satisfactory. The accounts accompanying the report show a balance of £14,193 available for division; and the Directors recommend the declaration of full dividends on all the stocks and shares of the Company.

BOURNEMOUTH GAS AND WATER COMPANY.—The half-yearly general meeting of this Company was held at the London Offices, 90, Cannon Street, E.C., last Friday—Mr. C. R. Mead in the chair. The Secretary (Mr. W. Cash) read the notice convening the meeting; and it was agreed to take as read the Directors' report and balance-sheet. The Chairman, in moving the adoption of the report, said it was a general thing for him to have the pleasure of presenting a favourable statement to the shareholders; and on this occasion he had to congratulate them on a more satisfactory condition of things than usual. The water-rental had increased to the extent of £369 beyond the amount for the corresponding half of last year; and the quantity of gas sold was nearly 13 millions in excess of that sold in the first half of 1887. He had pointed out, on former occasions, that it was to the advantage of the Company to study the interest of Bournemouth; and he was pleased to inform them that the Board had reduced the price of gas from 3s. 10d. to 3s. 6d. per 1000 cubic feet. This he was sure would be acceptable to the gas consumers of Bournemouth, and at the same time would enable the shareholders of the Company to divide 13 per cent. on the original capital, if it was considered desirable to do so. The report and accounts were unanimously adopted; and a cordial vote of thanks to the Directors and officers of the Company terminated the proceedings.

CARLISLE CORPORATION GAS AND WATER SUPPLY.—The gas and water accounts of the Carlisle Corporation for the past financial year will be presented at the next meeting of the Council. During the year £20,000 stock was created for gas-works purposes, £10,000 of which was to replace a mortgage; and out of the remainder certain sums have been paid into the city fund. The total income from the gas undertaking was £26,587; the total expenditure, £18,250. The profits therefore amount to £8337; leaving, after deducting the £2000 already paid into it, £6000 to go to the city fund. In the previous year the income was £25,608, and the expenditure £21,349; leaving £4258 of profits. So that the gas profits have been nearly doubled. In regard to the water accounts there was £20,742 stock created for water-works purposes and amount owing; and out of this sum there were mortgages amounting to £14,309 paid off. The total income for the year was £6934, and the expenditure £2546; leaving gross profits to the amount of £4388 to go to the district fund, under the new rule by which the profits will in future be paid over to that fund. In the preceding year the total income amounted to £6911, and the total expenditure to £3397; leaving gross profits to the amount of £3514. In the year 1886-7 a sum of £571 was deducted for depreciation; but under the recent resolution of the Council, such deductions, as in the case of the gas-works also, have been discontinued.

Miscellaneous News.

LIVERPOOL UNITED GAS COMPANY.

The Annual General Meeting of this Company was held last Tuesday—Mr. E. LAWRENCE in the chair.

The report presented by the Directors stated that the total revenue during the year ending June 30 last was £487,712 19s. 5d., and the expenditure £379,649 9s. 9d.; leaving a surplus of £108,063 19s. 8d., which had been transferred to the credit of the profit and loss account. After deducting the amount taken for the payment of the dividend declared last February, and the interest on the bond and debenture debt, there remained a balance of £44,095 8s. 5d. The Directors recommended the declaration of a dividend for the six months ending June 30 last of 5 per cent. on the ordinary consolidated stock, and 3½ per cent. on the 7 per cent. stock created under the Company's Acts of 1865 and 1882.

The CHAIRMAN, in moving the adoption of the report and accounts, said he did not think there was anything very special in the former to which he need call the proprietors' attention. The expenditure on the capital account had been very trifling; and, excepting for certain new mains, it involved only a sum of £4122 spent on the works. During the year it had been thought desirable to raise a certain amount of capital; and, as the shareholders were aware, there had been offered by auction £50,000 of the Company's "B" stock. The result of the sale was eminently satisfactory; the average price obtained being £153 5s. 1d. It might not be uninteresting to know that in 1883, when they sold stock by auction, the average price realized was £125 8s. 10d.; in 1884 it was £131 2s. 5d.; in 1885 it was £150 6s. 6d.; while this year it had risen to £153 5s. 1d. This, he thought, showed the satisfactory position in which the Company stood, and the confidence the public generally had in the undertaking. With regard to the revenue account, the total result would, he was sure, be felt by everyone to be satisfactory. It had resulted in a balance of £108,063 9s. 8d.; and, after paying the statutory dividends and the interest on the mortgage and debenture bonds, there was a balance remaining on the year's working of £6678 13s. 1d. Last year the accounts, it would be remembered, were not quite so satisfactory, inasmuch as on the twelve months there had been a deficit of £9000 on the working account—resulting from bad trade and a diminished consumption of gas in the town. The Directors felt then that there was no need to look upon this matter with anything like anxiety; and they came to the conclusion that there should be no alteration in the price of gas, trusting that with improved trade they would be able to wipe out the deficit. The consequence was that to-day it was wiped out, except the sum of £2329 11s. 7d.; and this small item, he might say with confidence, would totally disappear during the course of the ensuing year. Not only this, but he hoped that twelve months hence they would have a satisfactory balance in hand besides. Everything had been done to keep the works and the plant of the Company in the most efficient condition; and the working of the concern had been carried on in as economical a manner as in the past. Successful results had been achieved during the past year; and everything pointed in this direction in respect to the current year. In regard to the future, he did not like to indulge in prophecies, but he would just say that whatever progress the electric light might be making, at all events it had not interfered with the progress of gas. The two seemed to be going on side by side. If the supply of electric light was increasing, the increased demand for gas showed that there was an additional call for its manufacture. He was very much amused, when in London recently, on being told by a friend of his that a gentleman from Liverpool had said to him that the Gas Company were doing everything in their power to smother the electric light. He did not know what was meant by this; but he was not aware that the Company had taken any steps for the purpose of accomplishing such a thing, further than this—that if to continue their works efficiently and effectively, to produce and supply the public with a good, brilliant, and pure light, and to carry out their large undertaking economically, meant "smothering" the electric light, in that case he hoped they were doing it. In no other way that he knew of had they attempted to smother the light.

Mr. H. B. GILMOUR seconded the motion.

Mr. G. H. BALL asked what was the average cost per ton of the coal supplied to the Company, and said he also wished to have some information with regard to the tar contract.

The CHAIRMAN replied that the average price which they had paid for coal during the past year was, as nearly as possible, 10s. per ton; whilst the average price paid for cannel in the same period was about 19s.—making the average of both 14s. 9d. per ton. Their present tar contract was at 14d. a gallon.

Mr. BALL said in the face of this information he could not agree with the Chairman that the undertaking was worked on the most economical principles. If their coal was costing, on an average, 14s. 9d. per ton, they were certainly paying 2s. or 3s. a ton too much for it. He was able to speak with some confidence on this subject, because he had been connected with the gas undertaking of the Wallasey Local Board for the past nine years. There they had made a determined effort to get coals at as cheap a rate as possible; and the result was that the coal was now costing them about 11s. 9d. a ton, instead of 14s. 9d. as paid by the Liverpool Company. The illuminating power of the Wallasey gas was as high as that of the gas of the Liverpool Company. It was the duty of the shareholders not merely to pocket their dividends and be contented with them, but to see that the public were fairly considered in the matter. If the Company was worked on an economical basis, the price of gas might be substantially reduced; and his opinion was that they were not at present supplying gas at the lowest possible cost. For instance, they might get cannel at something like 12s. per ton, which would yield 33-candle gas. The tar contract was stated by the Chairman to be 14d. per gallon, and this was equivalent to about 17s. per ton; whereas in Manchester they were selling their tar at about 19s. per ton. He understood that their contractor had been favoured with some reduction with regard to tar in consequence of the low state of the market; but now that the price of tar was rising, it was only right that another rearrangement should be made with the contractor in the opposite direction.

The CHAIRMAN: What is the price of Wallasey gas?

Mr. BALL: I know it is 3s., whilst yours is only 2s. 8d. per 1000 feet. But you must remember that in Wallasey we pay something like 4½ or 4¾ per cent. dividend practically to our bondholders; and then we have a very large surplus which we apply to the reduction of our rates, so that the public get the full advantage of that.

The CHAIRMAN said the Directors were pleased with any suggestion tending towards the improvement of the manufacture of gas. At the same time he could not assent to Mr. Ball's conclusions; such, for instance, as the statement that from 12s. cannel they could get 33-candle gas.

Mr. BALL: What I meant to say was that the cannel was offered to Wallasey at less than 14s. per ton. I calculate that the carriage to Liverpool would be considerably less than with us; and therefore I am positive that you could get it for less than 13s.

The CHAIRMAN said he should still deny that they could obtain 33-candle gas from cannell purchased at 13s. a ton. The Directors fully realized that they were not merely trustees for the shareholders, but were also bound to do everything they could to provide the public with cheap gas. He maintained that they were doing so successfully. It was their duty to keep the illuminating power of their gas up to 20 candles; and if it fell a quarter of a candle below this, the Corporation complained that they were not doing their duty. It must be remembered that the quality of gas obtained from a certain material varied considerably with the weather; and it was necessary, therefore, for them to produce gas equal to 21 or even 21½ candles, in order that they might not fall below the standard. He denied that they used any richer material than was necessary to produce the desired results; and said that their Engineer (Mr. William King, M.Inst. C.E.) had devoted much time during the last few years to ascertain how far they could dispense with the use of superior material, and manufacture gas from less valuable coals. To some extent he had been successful; but it would be an absolute impossibility to carry it out to anything like the extent suggested. He assured Mr. Ball that the Directors, in making their contracts for coal, took every possible step to obtain at the very lowest price the material they required. Mr. Ball was inaccurate in his calculations with regard to the tar contract. The price which they obtained for tar was 20s. 4d. per ton—probably more than could be had under ordinary circumstances in the market. The contract referred to by Mr. Ball terminated last year; and the Company were now working upon a fresh contract.

The report and accounts were then approved.

The remaining business was of a routine character; the proceedings closing with the usual vote of thanks to the Chairman and Directors.

CROYDON COMMERCIAL GAS COMPANY.

The Half-Yearly General Meeting of this Company was held last Wednesday, at the Company's Offices, Katharine Street, Croydon—Mr. C. NEWTON in the chair.

The SECRETARY (Mr. W. J. Russell) read the notice convening the meeting; and it was agreed to take as read the Directors' report and the statement of accounts, an epitome of which appeared in the last number of the JOURNAL.

The CHAIRMAN said that it was now his duty to move the first resolution—"That the report of the Directors, with the accounts for the half year ending the 30th of June, 1888, showing a balance of £16,570 16s. 9d. available for dividend, be received and adopted." In submitting this resolution for the shareholders' acceptance, he said it would not be necessary on the present occasion to trespass long upon their time; for the past half year had not been a very eventful one, and the report and statement of accounts were so clear and satisfactory as to require very few observations in explanation. The Directors had upon the present, as they had upon nearly every previous occasion, to congratulate the shareholders upon the continued prosperity of the Company; and he hoped that this institution might be considered a permanent one. The shareholders would notice that the gas-rental received in the half year was about £600 less than in the corresponding period of 1887. The reduction of 3d. per 1000 cubic feet, which had taken full effect in the past half year, was equivalent to a loss of about £2200. This sum had been partially recouped, by an increased sale of gas of more than 10 million cubic feet, to the extent of £1500; leaving a deficiency of only £600, instead of £2200. Then with regard to the residuals, they had a very large increase in the sum-total; the increase being principally in coke—partly arising from the higher price they had received for coke, and partly due to the increased make, in consequence of the larger consumption of coals in producing the additional 10 million feet of gas sold. The amount obtained for residuals was £1700 in excess of the June half of 1887. On the other side of the account, the shareholders would see that they had to pay for the extra material and labour required to produce this greater quantity of gas. They would also notice that a very large sum had been spent in the half year for the repair and maintenance of the works. The Board deemed it advisable to put the works into a thoroughly efficient state of repair—not that they had fallen into a bad state—and he thought that the works would now compare favourably with any in the kingdom. They had taken advantage of the opportunity thus afforded of introducing some of the new engineering applications, which assisted them in the operations of manufacture. Consequently the gas for some months past had been of far higher illuminating power than in the previous few months, although then the quality of the gas as regards its candle power and its freedom from impurities was far in excess of the requirements of their Act of Parliament. It would further be noticed that a large number of stoves had been let out in the half year. Of course, these were perishable articles, and required a large sum to keep them in a state of repair. The working of the half year had produced a net profit which enabled the Board to recommend to the shareholders the payment of the usual dividends; and after doing so, and meeting interest on debentures and on the deposits for gas, they were enabled to carry forward about £242 more than they brought forward at the beginning of the half year. The amount of balance now being £16,600, and the sum carried forward after paying dividends being more than £6000, he thought with this large divisible balance, that if the present half year was as successful in its operations as the one which had just expired—and he had every reason to anticipate that it would be, from the experience of the last two months—when the Directors had the pleasure of meeting the proprietors again, the time would have arrived when the shareholders and the consumers would feel that they should have a further participation in the benefits which arose from this increasing prosperity of the Company.

Mr. W. HYSLOP seconded the motion, which was at once unanimously carried.

On the motion of the CHAIRMAN, seconded by Mr. MAONUS OHREN, Assoc. M. Inst. C.E., dividends were declared, payable forthwith, for the past half year, at the rate of 10 per cent. per annum on the capital of £51,600, and of 7 per cent. per annum on the capital of £137,500, and an additional dividend (under the sliding scale) at the rate of 3 per cent. per annum on the several classes of shares—all less income-tax.

Mr. HYDE, in proposing that the thanks of the meeting be given to the Directors and officers of the Company, said he thought it was scarcely necessary to say anything on that (the shareholders') side of the table. He might, however, remark that the accounts appeared to him to be an example of clearness and accuracy. The Chairman had told them that not only were they giving to the consumers a sum of upwards of £4400 a year; but, notwithstanding this, and notwithstanding the extent to which the electric light was being pressed forward, as well as petroleum (which he took to be a still greater enemy), they were enabled to carry over £242 more than they did on the last occasion. From this it appeared to him that the undertaking was being conducted in the most satisfactory way that it could be.

Mr. HALE seconded the motion, which was unanimously approved of.

The CHAIRMAN having suitably replied on behalf of his colleagues and the officers, the proceedings terminated.

TOTTENHAM AND EDMONTON GAS COMPANY.

The Annual General Meeting of this Company was held on Saturday last, at the Offices, Willoughby Lane, Tottenham—Mr. G. GARRE in the chair.

The SECRETARY (Mr. J. Randall) having read the notice convening the meeting, the report of the Directors and the statement of accounts, which were summarized in the JOURNAL last week, were taken as read.

The CHAIRMAN moved—"That the Directors' report and the statement of accounts for the half year ending the 30th of June, 1888, be received and adopted, and the report entered on the minutes of the proceedings of this day." He said that before he put the resolution to the meeting, he might perhaps be permitted to make a few remarks upon the report. As the shareholders would see, it was a short report; and he believed that all the Directors thought it was a very satisfactory one. Their view was to give a fair *résumé* of what had been done in the six months; at the same time not to elaborate, and perhaps puzzle the shareholders by too many details. The Directors, it would be seen, had been able to do that which he believed, just twelve months ago, the Board promised to do at the earliest opportunity—that was, to reduce the price of gas; and he hoped that they would be able to pay the proprietors the extra dividend at Christmas. The sale of residuals, they were glad to say, with the exception of tar (which continued very low), had improved in the last two half years. They had rather to mourn over the sale of coke; but with other residuals the markets had improved, and they had come out much better under this head than previously. Another pleasing thing he had to mention was that they were obliged to extend their mains to Winchmore Hill. The work was still in progress; but he believed, from what the Engineer (Mr. W. H. H. Broadberry) told him, in about a week's time the extension would be completed. The expenses for this work would come into the next half-yearly statement. In regard to the works, the Engineer reported that they were in excellent condition. They were now working up to the full power of the additions which they had made to the plant; and the time was not far distant when they would have to consider the question of further extensions if they continued at the same rate of increase. The increase had been at the rate of 8 per cent. per annum for the last three years—that was the absolute increase in the sale of gas in that period. The profit and loss account, including an amount of £3542 brought forward from the last half year, gave an available balance from which the Directors felt that they could recommend the payment of dividends on the original capital at the rate of 11 per cent. per annum, and on the new ordinary capital at the rate of 8 per cent. After paying these dividends, they would have left a balance of £3659; and this position was a vast improvement upon the one which he had to lay before the shareholders this time last year. They had then to trench upon their reserve to the extent of about £900. On this occasion, instead of doing that, they increased the reserve by £140 or £145. The next matter he had to refer to was the retirement of himself and Mr. Corbet Woodall; and when the time came, they would throw themselves upon the shareholders' generosity to reinstate them, and the same with Mr. Nicol, the retiring Auditor, who also offered himself. The dividends, he remarked, would be payable on Sept. 1.

Mr. J. MALCOLM seconded the motion, which was at once unanimously carried.

Mr. CORBET WOODALL proposed that dividends at the rate of 11 per cent. per annum on the original capital, and 8 per cent. per annum on the new ordinary capital, less income tax, be declared. He remarked that, after what the Chairman had said, in drawing a comparison between the condition of things in this and the corresponding half year, he was quite sure it would be satisfactory to the shareholders to know that the dividend had not only been declared but had been earned in the half year. It was also satisfactory to note that, while only this time last year they were nearly £1000 short of the dividend, yet the policy of the Directors within a few months after that time in recommending a reduction in the price of gas, had been justified by the balance-sheet which had been laid before them that day. There was one other point which he should like to bring before the shareholders. It was this—that while the reduction in the price of gas did justify an increased rate of dividend to be paid to the shareholders, it must be borne in mind that the divisible profits had now to provide not only the dividend, but also the reserve fund; and as new capital would shortly have to be raised (it was already overspent), if there was to be a reserve fund corresponding with the additional capital, it must be taken out of the profits that were otherwise divisible as dividends. He was sure that the shareholders would agree with him that while a large dividend was a good thing, so also was a good reserve fund as a matter of security for the value of the property. He considered that having works in a thoroughly good condition, and a reserve fund corresponding with the capital, was equally as valuable as a high dividend.

Mr. D. FORD GODDARD said he should have much pleasure in seconding the motion, the more so because, after having carefully examined the balance-sheet, he believed that the dividend had been earned in a thoroughly honest and substantial way. It seemed to him that all the essentials for earning a dividend in a company were present in the way in which this Company had been worked, as shown by the balance-sheet. There were one or two points which it was necessary to keep to the front, and which the Directors, as he gathered, had kept to the front—such as not unduly increasing the capital account. There was nothing which was so killing to a financial transaction as overburdening it with too heavy a capital. It did not appear to him that the Company was too heavily overburdened in this respect, as its capital per ton of coal was rather below than over the average of the London Suburban Companies. No doubt it would be necessary to increase the capital before long; seeing that the capital account, as Mr. Woodall pointed out, was already slightly overdrawn. He had, however, no doubt that the Directors would see that not more capital was raised than the transactions of the Company would bear. Another point which he noticed, and which was very satisfactory, was with respect to the maintenance of the works. Perhaps there was no greater temptation under the present Act or Acts under which gas companies worked in regard to the sliding scale than, with a view of increasing the dividend, to reduce the price of gas rather more than was perhaps wise or desirable; and to do so by letting down the works—or, in other words, "starving" the works—and not maintaining them at their full and proper value. The balance-sheet before them showed clearly that the works had been thoroughly well maintained; and what had been spent on repairs and maintenance had not been too much, but sufficient to keep them in good order. The Act offered vast temptations to spend too little on the works; but he did not think the shareholders in a Company like theirs would find fault with the Directors for laying out money in this department. Another point which gave him satisfaction was the fact that the general expenses seemed to be decreasing in proportion to the work done—not very largely, but still a little; and these little decreases gave them an indication as to the way the work was done. He noticed that the total expenditure on manufacture, distribution, and management of the works was a trifle less. It did not amount to much—perhaps 5d. per ton of coal carbonized. This was not large; but when they came to work it out to the amount of coal used, it meant a saving of something like £500, which was really to the

good. It was necessary that these small items should be constantly watched; so that they should not increase as they were apt to do. In regard to the residual products, these were also satisfactory. Gas companies owed more to these residuals than perhaps they gave credit for. It had been a serious loss to gas companies, the heavy fall in the price of residuals in late years. They welcomed the slight increase which was shown this year as a forecast of better times in this respect. He saw that there was about 6d. per ton increase in the residuals this year over last half-year's working. Considering all these points, and that the working of the Company seemed generally so satisfactory, they should have no hesitation whatever in accepting the dividend on that occasion. He had much pleasure in seconding the motion.

The motion was agreed to.
Sir H. E. CARTWRIGHT proposed the re-election of the Chairman (who was one of the Directors retiring by rotation). In doing so, he alluded to the great confidence the shareholders had in the concern, which, he said, was proved by the fact that hardly a share went into the market which was not sought after and acquired by someone interested in the Company.

The Rev. A. WILSON briefly seconded the motion, which was cordially confirmed by the shareholders.

The CHAIRMAN, in acknowledging the continued confidence reposed in him, remarked that this was the fifteenth year he had had the honour of being on the Board.

Mr. J. WARREN moved the re-election of Mr. Corbet Woodall, who also retired. He need only say that, from his practical knowledge of gas matters, Mr. Woodall was a very valuable colleague of the Directors.

Mr. J. B. DOE, J.P., seconded the motion, and it was carried.
Mr. WOODALL having returned thanks,

On the motion of Mr. GOULD, seconded by Mr. A. RICHARDS, the retiring Auditor (Mr. A. Nicol) was re-elected.

Mr. Nicol thanked the shareholders for his re-election; and took the opportunity of calling attention to the lectures on cooking by gas which had been delivered in the South Metropolitan Gas Company's district. He thought this was an excellent plan of increasing the consumption of gas; and, as a shareholder, suggested that they should do likewise.

Mr. A. G. HOUNSHAM, in a few appropriate words, proposed a vote of thanks to the Chairman and Directors.

Mr. KILSBY seconded the motion; and it was agreed to.

The CHAIRMAN having acknowledged the vote,
A similar compliment was paid to the Engineer, Secretary, and Officers of the Company, on the motion of Mr. HALL, seconded by Mr. GOULD.

The ENGINEER (Mr. W. H. H. Broadberry), in reply, mentioned that that was about the 29th half-yearly meeting at which he had stood before the shareholders to acknowledge their vote of thanks; and, speaking of the progress of the undertaking, he remarked that in 1874 the make was about 85 million cubic feet of gas in the twelve months; and last year it was 275 millions.

The SECRETARY remarked that Mr. Broadberry somewhat hesitated when giving the number of times he had stood before the shareholders. As for himself, he believed this was his 68th half-yearly meeting. He entered the Company's service in 1851; and hoped to still enjoy the confidence of the Directors for some time to come. He heartily thanked the shareholders for the vote they had passed.

The proceedings then terminated.

HASTINGS AND ST. LEONARDS GAS COMPANY.

The report of the Directors of this Company for the half year ending June 30 last, which is to be submitted to the shareholders at the ordinary general meeting to be held on the 6th prox., testifies to the satisfactory condition of the Company's business. During the half year the increase in the quantity of gas manufactured was at the rate of 7.21 per cent. over the corresponding period of 1887; and notwithstanding the reduction in the price of gas which came into operation on the 1st of January last, the gas-rental shows an increase. This, to some extent, has been due to the additional consumption caused by the exceptionally dull and inclement weather which prevailed for so long a period. As anticipated would be the case, the value of the residual products has improved still further. The extensions at the works, including the re-arrangement of and additions to the purifying and exhausting plant, and the fitting up of a portion of one of the retort-houses, are being proceeded with under the direction of the Engineer (Mr. C. E. Botley, Assoc. M. Inst. C.E.), so as to be ready for the winter's requirements. The £10,000 of additional capital sanctioned at the last meeting has been issued, and realized a premium of £6834 15s. The Corporation of Hastings have appointed a Gas Examiner, according to the Act of Parliament, who has reported satisfactorily on the quality and purity of the gas supplied by the Company. The accounts accompanying the report show a profit balance of £8880 13s. 2d. for the half year, which with the balance brought forward amounts to £22,991 3s. 6d. to be dealt with by the shareholders; and it is proposed to pay a dividend at the rate of 11½ per cent. per annum on the £25 shares, and 8½ per cent. per annum on the £20 shares, and to carry forward the remainder.

SUTTON GAS COMPANY.—The Directors of this Company report an increased sale of gas to the extent of nearly 2 million cubic feet in the six months ending June 30 last, as compared with the corresponding period of the previous year. This is attributable to the exceptionally dark and cold weather which prevailed throughout the past half year. The Company are about to erect new offices, to meet increasing requirements. Dividends at the rates of 10 and 7 per cent. per annum are recommended.

THE LONDON COAL AND WINE DUES ACCOUNTS.—The annual accounts of the Chamberlain of the City of London relating to the coal and wine dues have just been published. The gross amount of duty on coals brought into the Port of London was £176,367; brought by railway conveyance, £220,045; by inland navigation, £418; and by road traffic, £586—total coal duty, £397,418; wine duty in the Port of London, £9573; grand total, £406,991. Of this £328,798 was paid into the Bank to the credit of the Metropolitan Board of Works, to the account of the Thames Embankment and the Metropolis Improvement Fund. The City's duty on coals was £176,630.

CHESTERFIELD WATER AND GAS COMPANY.—The half-yearly meeting of this Company was held last Friday—Mr. R. T. Gratton presiding. The accounts showed that the receipts from the sale of water in the six months ending June 30 last had been £3154, and from gas £4490; the total income, including £484 for coke and other residuals, having been £8136. The cost of the manufacture and distribution of gas had been £1616. The total expenditure had been £5591, leaving a balance of £4545 to be carried to the net revenue account. After paying the interest on mortgages and calls in advance, there was a net profit for the six months of £4151, which is £479 in excess of the amount for the corresponding half of last year. A dividend at the rate of 5 per cent. per annum on both ordinary and preference shares and stock was declared; and there will be a balance of £252 to be carried forward.

LANCASTER CORPORATION GAS SUPPLY.

STATISTICS OF THE GAS DEPARTMENT FOR THE YEAR ENDING JUNE 30.

The Gas Engineer of the Lancaster Corporation (Mr. C. Armitage, F.C.S.) has favoured us with a copy of the report he has lately presented to the Gas Committee on the work of the gas undertaking during the twelve months ending June 30 last. It shows that the receipts amounted to £16,284 15s. 9d., and the expenditure to £9910 18s. 3d.; leaving a gross profit of £6373 17s. 6d. After deducting interest on stock and mortgages, addition to the sinking fund, &c., £4629 8s. 10d., there was left at the close of the financial year a net balance of £1744 8s. 8d. This is an increase of £393 11s. 7d. over the previous year's surplus profit, notwithstanding the reduction of 3d. per 1000 cubic feet made from July 1, 1887. The sale of gas to private consumers produced £9845 19s. 9d.; and the principal item of expenditure was, of course, for coal—£5729 15s. The receipts for residual products amounted to £3873 15s. 4d.; being equal to 67.70 per cent. of the total cost of coals. In other words, coal and cannel cost an average of 12s. 9d. per ton, and the products realized 8s. 7d. per ton; leaving the net cost of coal 4s. 2d. per ton. The quantity of gas made was 89,150,000 cubic feet (an increase of 11,541,000 cubic feet, or 14.81 per cent., as compared with the year 1886-7); the quantity sold and used was 86,214,562 cubic feet—leaving 3,29 per cent. unaccounted for. The amount expended on capital account up to June 30, 1883, was £101,124 18s.; and nothing whatever has been added to this account since. The reserve fund now amounts to £680 0s. 7d., and is on loan to the Water Department, at 3½ per cent. per annum; the interest being added yearly. The sinking fund now amounts to £3592 7s. 7d. During the past year, renewals and extensions were made, and charged to the renewal account, to the amount of £530 6s. 5d.; leaving a balance of £240 14s. 10d. on that account. The total amount received for gas was £11,171 3s. 10d., less the cost of lighting, extinguishing, cleaning, and repairing the public lamps, £343 8s. 3d.; making £10,827 15s. 7d., which is equal to 2s. 6.35d. per 1000 cubic feet of gas sold. This sum may be apportioned as follows:—Cost of gas, 1s. 0.99d.; interest and sinking fund, 1s. 0.47d.; profit, 4.89d. New mains cost £470 5s. 10d.—equal to 1.31d. This is charged to the revenue account, but could legitimately be charged to capital account; thereby reducing the net cost of gas to 11.68d. per 1000 cubic feet of gas sold. This cost, Mr. Armitage thinks, will bear favourable comparison with any gas undertaking. He closes his report as follows:—"If a further reduction in the price of gas be now made, I would recommend that the gross price be 2s. 6d. per 1000 cubic feet, and to allow a discount of 10 per cent. for prompt payment (or, say, if the account be paid before the expiration of 28 days from the date of delivery); making the net price 2s. 3d. This reduction would cause a decrease of £1087 in the gas-rental, providing the consumption of gas should remain stationary during the coming year, which is very improbable. An increase in consumption may be expected, in consequence of the reduction in price—all previous reductions having had a similar effect; and, in my opinion, this will be no exception to the rule, as the demand for coal gas is becoming more popular, and the consumption is increasing every year."

Appended to the report are the following statistics:—

	Cubic Feet.
Gas made as per station meter	82,150,000
„ sold to private consumers	77,922,500
„ sold for public lighting	7,694,862
„ used on works and offices	597,200
	86,214,562
Unaccounted for	2,935,438
or 3.29 per cent.	
Capital employed—	
Stock capital	£82,500
Loan „	20,400
	£102,900, or £11 9s. 5d. per ton of coal, or
	£1 4s. 0d. per 1000 feet of gas sold.
Coals carbonized—	
Common	5025 tons=56 per cent.
Cannel	3944 „ =44 „
	8969 tons.
Illuminating power required by Act.	14 candles
Illuminating power supplied	20 „
Gas made	89,150,000 cub. ft.
„ per ton of coal	9.939 „
Gas sold	85,617,362 „
„ per ton	9.545 „
„ per cent. on make	96.03 per cent.
Used at works and offices	597,200 cub. ft.
„ per cent. on make	0.66 per cent.
Gas unaccounted for	2,935,438 cub. ft.
„ per cent. on make	3.29 per cent.
Coke made	5,890 tons.
Coke used for fuel (including boilers)	1,523 „
„ per cent. on make	26.12 per cent.
Tar made—575 tons (195 gallons per ton)	112,125 gallons.
„ per ton of coals	12.5 „
Liquor made—1336 tons (218 gallons per ton)	291,248 gallons.
„ per ton of coals	32.47 „
Net proceeds of coke and other residuals per cent. on cost of coal	67.60 per cent.

At the Meeting of the Town Council last Wednesday—the MAYOR (Alderman Blades) in the chair—the report and accounts above referred to were under consideration.

Alderman HATCH, in moving the confirmation of the minutes of the Gas Committee, remarked that as this was the annual meeting, at which the condition of the gas undertaking came under review, he would say a few words in reference to the various matters mentioned in the minutes. Coming to the Gas Engineer's report, he said it would be within the recollection of the Council that twelve months ago the price of gas was reduced to 2s. 6d. per 1000 cubic feet all round. The Committee had every reason to congratulate themselves upon the results of the resolution the Council came to on that occasion. There had been a considerable increase in the make and consumption of gas during the past twelve months, and they had realized a larger profit than they did the year before. In weighing matters over, the Committee thought they could not do better with the surplus they had in hand than place it to the renewal fund; and they asked the Council to confirm the resolution that the sum of £1700 odd be added to that fund. They were now engaged in a very expensive work—viz., in putting down new purifiers. The whole of the ironwork was already on the ground, the foundations were laid, and they were ready to carry it to completion. He was proud to say that they had in Mr. Armitage a very efficient Manager; and but for his efficiency they would perhaps not be in the good position they now occupied. They paid him a fair salary, and they did not interfere with him continually in suggesting this and suggesting the other thing in matters they knew very little about; and while they congratulated themselves upon having a good Manager, Mr. Armitage might congratulate himself likewise upon having good masters. He proposed the confirmation of the minutes; and he hoped the time was not far

distant when they would be enabled to enter into the question of abolishing the meter-rents, and not only that, but be able to effect a further reduction in the price of gas to 2s. per 1000 cubic feet. For the present, however, they must satisfy themselves with a reduction of the price to 2s. 3d.

Mr. WATSON seconded the motion.

The Mayor asked if anyone had an amendment to propose; remarking that the matters referred to by Alderman Hatch were both very good and very numerous.

No one answered for the moment; but just as the Mayor had indicated that the minutes were passed,

Mr. BELL rose and claimed to be heard.

After some conversation on the point, his Worship allowed this.

Mr. BELL said he considered it must be very satisfactory to all of them to have so excellent a report on the result of the working of the gas undertaking, which reflected great credit on their Gas Manager. Last year they granted a reduction which cost them £1000; and notwithstanding this, they had in the present year a profit of £400 over that of last year. It must also be gratifying to the older members of the Corporation, who were bold enough some six or seven years ago, and in the face of a great deal of outside opposition, to purchase the gas-works, to find that it had been a capital speculation for the town ever since, instead of the loss which some people predicted it would be. With regard to the proposals made by the Chairman of the Committee, he was sorry he was not altogether in accord with him. He (Mr. Bell) would like to have seen the meter-rents abolished, because in his opinion it would act as a greater stimulus to the increased use of gas than a reduction in the price. He believed there were a good many cottagers who were not now using gas, and who looked at the expense of having a meter being put into their houses and then having to pay for the meter; whereas if it could be put in free of cost, and they had only to pay for the gas consumed, many would be inclined to use gas who now did without it. Another objection he had was as to the reduction in the price of gas to those who lived outside the limits of the borough. These outsiders had no liability in respect to any risks connected with the gas-works; and if the electric light or anything else should supersede gas, every fraction of the loss would fall upon the ratepayers. It was not right, just, or proper to the ratepayers that outsiders should have gas at the same price as those resident in Lancaster, seeing that the latter were liable for the whole of the risk. Although he was not one to advocate the employment of any part of the gas surplus in reducing the rates of the town by one farthing, yet he thought the Committee might have seen their way to reduce the price of gas supplied for the public lamps. This would have been a public benefit. Alderman Hatch told them distinctly last year, when the price was reduced to 2s. 6d. per 1000 cubic feet, that next year, if they had a surplus, they would not only make a reduction in price, but it was their intention also to improve the quality of the gas to the extent of two candles, which would cost £1000. He thought they all knew that the gas in Lancaster was very cheap, and would compare favourably in this respect with that supplied in any other town. But he should like to draw the attention of the Council to the renewal fund. This fund now stood at something like £240; and to this it was proposed to add £1744, the balance this year. But it was a fact that every farthing of this fund, if not already spent, would go—the great proportion in providing new purifiers, and the other towards new mains; so that the renewal fund would only stand at £200, whereas a few years ago it was £1500. It was all very well to "go with the stream" in reducing the price of gas, and that sort of thing; but supposing the price of residuals went down, what would they do then? Most of their profits during the past year had really been made out of an increase in the price of residuals—an increase in the price of chemicals. Supposing next year they went down, what would be the result? Why, they would have to increase the price of gas. But his principal objection was to reducing the price of gas to outsiders, especially when it happened that they did not share any of the risks which might fall on the ratepayers.

Mr. HARRIS asked what the Committee proposed to do with regard to those consumers who had their own meters.

Mr. BAILEY said the question of reducing meter-rents had been taken into full consideration by the Committee, but they found they were not in a position to deal with them at the present time. They decided, however, that during the coming year a scheme would be propounded whereby they expected to carry out to a considerable extent what Mr. Bell had put forth in regard to the abolition of meter-rents. As to the increased cost of residuals, the Manager informed them that the percentage of increase was not greater appreciably than in the previous year; and therefore their profits had not been provided out of the additional amount obtained from residuals, as stated by Mr. Bell. The chief profit had been made from the augmented consumption of gas; so that although they had had a reduction during the past year of 3d. per 1000 cubic feet, there had nevertheless been an increase of something like £400 more than in the preceding year. If it was the same next year, they hoped to be able to abolish the meter-rents, and have something in addition to put to the renewal fund.

Mr. MOLYNEUX wished to congratulate the Gas Manager and the Gas Committee also on the highly successful results of the year's working of the Gas Department, which had demonstrated to a good many people that what was thought to be a bad "spec" was an exceedingly good one. He agreed with the remarks of Mr. Bell as to their not supplying gas at the reduced rates to the out-townships; but he could not help being a little amused at that gentleman's remarks, when, after saying he was opposed to any portion of the gas profits being applied to the reduction of the rates, he very ingeniously went on to argue that the cost of lighting the public lamps should be taken out of the gas profits. He (Mr. Molyneux) took it that if there was a reduction in the price of gas supplied to the public lamps, it would result in so much being taken off the rates on that account. It might be a roundabout way of doing it; but it amounted to the same thing in the end.

Mr. WATSON said with regard to the question of supplying gas to the out-townships at a reduced price, they would cease to be out-townships soon; and he did not see that the Council could do otherwise than let these places have gas at the same price as they paid in the borough.

Mr. KITCHEN, while expressing satisfaction with the report, considered with Mr. Bell that the ratepayers of Lancaster were responsible for the working expenses, for the purchase money, and for all risks connected with the gas undertaking, whilst those residing outside the borough had no such responsibilities attached to them; and this made all the difference between raising the price of a commodity and reducing it. He proposed, as an amendment, that the words "to residents within the borough" be added to the resolution of the Gas Committee recommending a reduction in the price of gas.

Mr. MOLYNEUX seconded the amendment.

Alderman PRESTON considered that the question of a reduction in the price of gas had been set up as against the meter question; and for his own part he would be glad if the meter-rents could be done away with altogether. In considering the matter in Committee, there was a strong desire to reduce the price of gas, and hopes were held out that at some

future day the meter question would have the attention of the Committee. If they went on reducing the price of gas (say) by 3d. per 1000 cubic feet every year, as they had been doing, they would get it to such a figure that they would be unable to abolish the meter-rents, from which they now derived about £500 a year. What they all wanted to do, he hoped, was to induce poor people to take gas, and use it for other than simply illuminating purposes, instead of, as now, remaining without it because they had meter-rent to pay. They had to pay for the meter in the summer months, when it was not in use, just the same as in the winter time. It might be said that it made little difference whether they had it "in meal or in malt;" but bearing in mind the great number of people who would be gas consumers were it not that they had an objection to pay meter-rent, it would be policy on their part to abolish this charge altogether. The difficulty seemed to be how to deal with those who had their own gas-meters. This was a matter which they would have to discuss with the Gas Manager; and seeing that he had shown such practical knowledge on everything connected with the supply of gas, this question also would not doubt receive a satisfactory solution at his hands.

The Mayor said it was quite evident that the amendment was aimed at the Lancaster Waggon Works; and he asked if it would not be wise to extend the reduced price to them, seeing that they were one of the largest consumers of gas.

Alderman HATCH, in reply, said some of his remarks had been anticipated by previous speakers. The amount received from meter-rents was £511 per annum, but a great difficulty in abolishing these rents presented itself in regard to those who had their own meters. These were the largest meters; and their owners generally were the largest consumers the Gas Department had. Their Manager had suggested a scheme which it was thought might be a way out of the difficulty. He had calculated that the life of a meter was 15 years. In other words, if a meter was worth £15 when new, it was worth £1 less for each year it was used. This was probably the basis on which the question of abolishing the meter-rents would have to be considered. The Mayor had just touched on the question of supplying outsiders with gas at the reduced price, and at what those who were opposed to it were aiming at. He (Alderman Hatch) was fully convinced, as an old tradesman, that it would be the most suicidal policy on their part if they said they would only supply Lancaster at the reduced price, and not take in the outsiders. They must remember that the Gas Department was a commercial concern only. If a customer came into any of their shops, they did not ask him if he lived in Lancaster, or whether he came from one of the out-townships. Nor, if they found he did so, would they charge him any more than if he had lived in Lancaster. No; they asked him just the same price, and they charged just the same for his goods as they did anybody else. Hence he maintained that the outside customers were really a benefit to them; and they ought to increase their number in every possible way, and encourage them to consume as much gas as they could. Mr. Bell had referred to a remark he (Alderman Hatch) made last year as to increasing the illuminating power of the gas. He might inform him that they had done so, and that they were using considerably more candle this year than they had done before. The Manager had endeavoured to improve the illuminating power of the gas, and the Committee considered he had been successful in so doing.

Mr. KITCHEN said he was astonished to hear the Mayor say the remarks in reference to the reduction in the price of gas to outsiders were aimed at the Waggon Works. He did not consider they were aimed at any particular place.

The amendment was then put, and lost by 7 votes to 12; the motion for the confirmation of the minutes being subsequently carried.

EDINBURGH AND LEITH GAS COMMISSION.

At the Meeting of the Edinburgh and Leith Gas Commission on Monday last week—the Lord Provost (Sir J. Clark) in the chair—the Clerk (Mr. Jack) read the decision of Mr. G. Livesey, C.E., the Arbitrator, upon the questions submitted to him, as to what implements were to be specially paid for by the Commissioners, in terms of the Act of Parliament, and what sum was to be paid for the stock of coal which the Companies held at the time of the transfer. Mr. Livesey's award (the substance of which was given in the JOURNAL last Tuesday) was as follows:—"I, George Livesey, of London, C.E., having been appointed sole Arbitrator to determine not only the price to be paid by the Edinburgh and Leith Corporations' Gas Commissioners for the items or articles referred to in section 20 of the Act, but, secondly, whether any items or articles fall or do not fall to be valued and paid for; and, having heard the representatives of the parties who have requested a decision on the second point before proceeding with the valuation, I hereby declare that no item or article is to be valued and paid for which was used or required for the efficient working of the respective undertakings at their maximum production of last winter; and I also declare that only those stores of materials referred to in section 20 of the said Act, and all implements, meters, and pipes in store or in hand—whether new or unused or not—which are in excess of the quantities of materials, implements, meters, and pipes which were required at the aforesaid period of maximum working, are to be valued and paid for, as provided in the said Act." On the recommendation of the Works Committee, it was resolved to appoint Mr. Dewar, the Statutory Clerk of the Leith Company, Superintendent Surveyor for the Commission. The Committee reported that they had authorized Mr. R. Mitchell to take charge of the mains and services south of Queen Street, and Mr. F. T. C. Linton those north of that thoroughfare. The Clerk read a letter by Mr. Blair (the Agent of the Edinburgh Company), accompanying a statement showing the total amount payable by the Commissioners to the Company for capital expenditure and gas supplied to the consumers since the last accounts were rendered, to be £2776 12s. 6d. Annexed to the statement were details of the other items, duly certified by Mr. Mitchell. For convenience, he added to the statement a note of the amount expended in connection with the gasholder tank at Meadowflat, and which sum is, by arrangement, also payable by the Commissioners. The letter was remitted to the Works and Finance Committees. The Lord Provost moved the appointment of Mr. Wodrow Thomson, of the Edinburgh Gas Company, as Auditor of the Commission. Mr. Smith Clark thought the best plan would be to have an entirely fresh mind introduced into the concern. Mr. Colston said this was exactly the view he himself had taken, and in that respect he would suggest the name of Mr. Molleson. Mr. Smith Clark said this was "jumping out of the frying-pan into the fire." It was quite evident that in discussing matters of this kind in public they were treading upon delicate ground. He thought the appointment was one of very grave importance, and therefore suggested that the matter should be remitted to the Finance Committee for consideration and report. After some conversation, a vote was taken, when 11 were in favour of the appointment, and 4 for reference to the Committee. In view of the large vote in favour of Mr. Thomson, he was declared to be elected. The Finance Committee were empowered to obtain a loan to the amount of £25,000 or £30,000 to pay for stores.

THE EXAMINATIONS IN "GAS MANUFACTURE."

In the JOURNAL a fortnight ago (p. 294) we gave a list of the successful candidates at the examinations in "Gas Manufacture" held by the City and Guilds of London Institute in May last. It will doubtless be interesting to many of our readers—especially those who contemplate submitting themselves for examination—to give the papers set in the two grades, in order that they may form an idea of the questions put by the Examiners (Messrs. R. Morton, T. Newbigging, and C. Hunt). We may mention that there were 45 candidates examined, of whom 24 failed to satisfy the Examiners. The following were the questions; the time allowed for each paper being three hours:—

Ordinary Grade.

1. Give a sectional sketch of a hydraulic main and dip-pipe. Explain the use of this arrangement. 2. Describe the exhauster, either rotary or reciprocating, and state the reasons for using it. 3. What useful purpose is served by the bye-pass mains and valves in connection with the apparatus of a gas-works? 4. Explain the difference between a "single-lift" gasholder and a "telescopic" gasholder. 5. Exclusive of the crown, what are the cubical contents of a gasholder 100 feet in diameter by 20 feet deep? 6. What are the disadvantages of charging retorts with coal in a wet condition? 7. A station meter registers 50,000 cubic feet at a temperature of 50° Fahr. What would this amount to corrected to 60° Fahr.? 8. What are the simple tests generally used to discover the presence of (a) sulphuretted hydrogen, (b) ammonia, and (c) carbonic acid in coal gas? 9. Describe what is meant by the term "8-oz. liquor." 10. A main from which there is no consumption is supplied with gas from the works at 10-10ths pressure. It rises 100 feet, and afterwards descends 50 feet. What would be the pressure recorded at these two levels?

Honours Grade.

1. In an ordinary retort-setting, what are the principal conditions to be observed with the object of securing the highest efficiency with the greatest economy of fuel? 2. What relation should the fall in works' mains have to the flow of gas passing through them? Give reasons. 3. What is the effect of the exhauster upon the temperature of the gas as between the inlet and outlet? Give explanations. 4. Under what varying conditions do the purifiers raise or lower the temperature of the gas passing through them? 5. A hydraulic main has twelve ordinary dips, 6 inches in diameter, working with a 1½-inch seal. What must the surface area of the liquor be to enable it to withstand a back pressure of 40 inches and nothing more? 6. Of a ton of average quality bituminous coal, carbonized in the ordinary way, what proportion, by weight, would be recovered in the solid, what in the liquid, and what in the gaseous form? Answer in general terms. 7. Find the value of a ton of coal, in pounds of sperm, which yields 10,240 cubic feet of gas, having an illuminating power equal to 16½ sperm candles. 8. At what temperature and barometric pressure is gas said to be at its "standard volume"? Why is it desirable that it should be reduced to such volume on its measurement by the station meter? 9. What number of stokers do you consider should do the work of carbonizing 150 tons of coal per 24 hours, each man attending to his own firing, wheeling his own coal from an adjacent store, and removing his surplus coke to the outside of the retort-house? 10. Name the crude products of the first distillation of coal tar, and state their principal uses.

It may not perhaps be out of place to mention here that the first prizeman in the Honours Grade (Mr. W. R. Herring) is draughtsman and an assistant to Mr. C. E. Botley, Assoc. M. Inst. C.E., Engineer and Manager of the Hastings Gas-Works; while the latter gentleman's son (Mr. C. F. Botley), who is in the locomotive shop at the Great Western Railway works at Swindon, carried off the first prize in the Ordinary Grade. Mr. Botley is to be congratulated on the success achieved by his son and assistant; the more so in view of the fact that a former assistant (Mr. F. G. Dexter) took the first prize while he was with him, and has come off with high honours at South Kensington.

KILMARNOCK CORPORATION GAS SUPPLY.
ANNUAL REPORT.

The decision of the Kilmarnock Town Council to reduce the price of gas to the consumers to the extent of 5d. per 1000 cubic feet—from 3s. 11½d. to 3s. 6½d.—has already been mentioned in the "Notes" of our Glasgow Correspondent; and we now proceed to summarize the report and financial statement for the year ending June 14, 1888, which were presented to the last meeting of the Town Council by the Gas Committee. In the financial part of their report, they state that the gross revenue amounts to £12,060 11s. 6d.; and the gross expenditure to £8411 10s. 2d.—leaving a surplus of £3649 1s. 4d. Out of the latter the following sums have been provided:—Sinking fund for payment of mortgage debentures, £2000; gasholder extension, part payment, £650; accounts for gas and meter rents irrecoverable (less old arrears recovered), £61 6s. 11d.—making a total of £2711 6s. 11d.; and leaving a balance of £937 14s. 4d. Adding to this the balance at the credit of profit and loss account at June 14, 1887 (£8675 6s. 4d.), gives a sum of £9613 0s. 8d. to be carried to the next accounts. Of this sum, however, £7459 has been expended in maintenance of the works.

Speaking in reference to the works, &c., the Committee state that the gas manufactured, as per station meter, shows an increase for the year of 2,212,900 cubic feet, while as regards the amount of gas sold there was an increase of 1,770,650 feet. The leakage or unaccounted-for gas was at the rate of 10½ per cent., as compared with 10 per cent. in the year 1886-7. On the wages account there was a decrease of £61 18s. 8d. Notwithstanding the fact of there being such a large increase in the production of gas, there was a decrease in the coal account, amounting to £144 3s. 7d. Owing to the increased value of the bye-products, the revenue from the chemical works during the past year was £317 greater than that of the preceding year.

Under the head of expenditure, there was an outlay for coals of £3284 8s. 8d., which, with the amount spent for lime, retorts, and dross, was brought up to £3530 8s. 4d. For pipes and meters there was expended £325 11s. 9d.; for repairs, £201 13s. 7d.; for salaries, £566 2s.; for wages, £1603 1s. 2d.; for income-tax, rates, and other charges, £698 0s. 1d.; and for interest on mortgage debentures, £1315 15s. 11d. Collectively, these (with various minor items) make up a total expenditure of £8411 10s. 2d.

As regards revenue, the gas sold produced £10,694 14s. 11d.; meter-rental, £255 1s. 11d.; and tar, &c., £859 19s. 10d.—the total revenue amounting to £12,060 11s. 6d. It will thus be seen that the excess of revenue over expenditure, carried to profit and loss account, amounts to £3649 1s. 4d. The balance on June 14, 1887, was £8675 6s. 4d.; the arrears recovered during the year amounted to £1 4s. 11d.; and with the profit, there was a grand total of £12,325 12s. 7d.

In the shape of liabilities, there are the mortgage debentures amounting to £33,025; deposits from gas consumers, £23 10s. 6d.; sundry accounts unpaid, £168 8s. 9d.; and profit and loss account, £9613 0s. 8d.;—making in all, £42,829 19s. 11d. Then as assets, there are the gas-works and plant valued at £36,436 1s. 1d.; stock of materials on hand, £433 7s. 3d.; various outstanding accounts—for gas, meter-rents, tar,

&c.—amounting to £514 13s. 1d.; cash on deposit in bank, £3500; and cash on current account, £1938 7s. 9d. These, with the cash in hand, collectively make up a total of £42,829 19s. 11d.

The total quantity of gas manufactured during the year was 60,192,600 cubic feet; and the total quantity of coal carbonized was 6177 tons. The gas produced per ton of coal was 9726 cubic feet.

It is gratifying to know that the Gas Committee have been so efficiently served by Mr. J. Fairweather, the Manager, that they have recommended an increase to his salary amounting to £40 per annum, and that their recommendation has been approved of by the Town Council.

PARTICK, HILLHEAD, AND MARYHILL GAS COMPANY
LIMITED.

The annual report of the Directors of this Company, with the balance-sheet for the year ending June 30 last, has just been issued to the shareholders, who will doubtless be gratified that the Company's business, under Mr. Levi Monk's management, continues to exhibit a progressive improvement. In view of the probability of the accounts showing a surplus of revenue available for dividend, the Directors state that they considered it proper to take the opinion of the Court of Session on the question of the right of the preference shareholders to arrears of dividend for the years ending June 30, 1886 and 1887. A special case was accordingly entered into, between the Company on the one hand, and two of the preference shareholders on the other hand, which was heard before the Judges of the First Division of the Court of Session in May last, with the result that the Court unanimously found (1) that the preference shareholders were entitled to the arrears of their dividend for those two years, but (2) that they were not entitled to interest on the arrears. This decision is appealable to the House of Lords; but, in accordance with the legal advice which they have received, the Directors recommend that the case should not be carried further. The net profit for the year, after payment of all debenture interest, and providing for interest on the reserve and depreciation funds, amounts to £10,445; out of which the Directors have carried to the depreciation fund £3000; leaving a balance of £7445. They recommend that this amount should be disposed of in the following way:—To extinguish the balance at the debit of the suspense account, £1942; in payment of cumulative dividends at the rate of 5½ per cent. (less income-tax) to the preference shareholders for the years ending June 30, 1886 and 1887, in terms of the decision of the Court of Session, £3300; in payment of dividend at 5½ per cent. (less income-tax) on the preference shares for the year ending June 30 last, £1650. This will leave about £553 to be carried forward. The Directors remark that the works have been, as usual, maintained in a thoroughly efficient condition out of revenue. The quantity of gas made during the year largely exceeds that of the previous year; and to meet the additional requirements of new consumers, the Directors have found it necessary to contract for an additional gasholder, which will be ready for use in the coming winter. The revenue account shows the total expenditure to have been £23,112, and the income £36,358; leaving a balance of £13,246 to be carried to the profit and loss account. The general balance-sheet shows the capital and liabilities to amount to £202,788. Up to the present, the outlay for the construction of works and additions during the past year amounts to £78,100. The works in progress are valued at £2506. For pipes and cost of laying there has been an outlay of £81,874 17s. 5d.; and for meters, £19,699 4s. 6d. On the gas-stove department there has been expended £1429 13s. The stores on hand at June 30 are set down as valued at £2934 0s. 9d. Various other items, including the cash at bankers, in the suspense account, &c., bring up the property and assets to the value of £202,788—the amount above named.

SOUTH STAFFORDSHIRE WATER COMPANY.

The Half-Yearly General Meeting of this Company was held last Thursday, at the Queen's Hotel, Birmingham—Mr. F. JAMES in the chair.

The notice convening the meeting having been read, the report of the Directors, which was given in the JOURNAL for the 14th inst. (p. 307) was presented.

The CHAIRMAN, in moving the adoption of the report and accounts, said it was satisfactory to know that the water of the Company was being laid on to 1500 additional houses. This made a total of 65,641 houses now supplied by them, out of about 110,000 houses in the district. There were probably 15,000 or 20,000 houses that would sooner or later be connected with the mains. The gross amount of water-rates for the half year ending June 30 last was £33,973, as against £32,707 in the corresponding period of 1887. The expenditure on capital account during the half year was £5000; this being the cost of 4½ miles of mains. There was due to bankers and others £5594; but in the revenue account there was a balance of £12,000 in the bank. With regard to the profit and loss account, the half-year's water-rates were £33,973, as against £32,707; and the amount for service-laying—£293—was pretty much the same as last year. On the opposite side of the account, the engine charges were a little in excess of the first half of 1887; but this was accounted for by the additional quantity of water pumped. The maintenance of works was considerably in excess, owing to the repair of one of the reservoirs. In the first instance it was decided to take any risk of damage that might arise through the mining operations in the district; but it was a question whether the Directors ought not to begin to set aside something as a maintenance fund against accidents that might occur. If there were no extra charges under this head during the present half year, the Board would probably put by something as the nucleus of a reserve fund. The rates—an ever-increasing item—had risen from £2391 to £2618; and the balance carried down was £13,130, against £13,274 in 1887. An exceptional charge on the debtor side was that of £1574 for law expenses, which were usually about £74. The increase was due to the promotion of the Company's Bill to equalize their charges. If the application had been successful, the entire cost would have come out of capital; but as it had failed, the expenses had to be borne by the revenue. Until very recently the Directors had not full knowledge as to what these expenses would be. They found, however, they were in excess of what they expected; the total parliamentary charges not being less than £3500. Had there been a local inquiry, the cost would then have been very much less; and he thought there would have been a better appreciation of the result. The Directors proposed to wipe off £1500 in the half year just ended, and spread the remainder over the next two half years. Speaking of the Bill, he might say the Directors expected reasonable and legitimate opposition; but they did not anticipate some of the opposition which was brought forward. The Bill entered the House of Lords on the 12th of March; and the Directors voluntarily made the concession of substituting 1s. 6d. and 1s. 10d. per quarter for 2s. 2d. per quarter in regard to certain houses in their schedule of rates—an alteration which meant an adverse sum of £1200 a year to the Company. In this form the Bill passed the Upper House; and the Directors were hopeful that they would not be subjected to the same amount of opposition before the Committee of the House of Commons. Some of the opponents withdrew; but three of the Local Authorities continued strenuously to oppose—viz., the Corporations

of Walsall and West Bromwich, and the Local Board of Rowley Regis. The Bill did not get into the Commons Committee until the 9th of July, which delay meant additional expense; and then there was a great amount of opposition—one of the grounds being the quantity and quality of the water. He here read a portion of the evidence given before the Committee on the question of the purity of the water, and remarked that no water company could avoid the water occasionally appearing "dirty," as it was sometimes called. The greatest opposition came from the Walsall Corporation, who set out in the first instance that the Company wanted to increase the rates in Walsall by something like £1000 a year. Their own evidence showed the increase only to be £320, or something like 5d. per house. But the Corporation did not tell the whole truth. They said nothing about the advantage of the £1700 a year they obtained by a fluke as to the meaning of the words "annual value." The Town Clerk said they wanted the Company to keep to the bargain of 1863. He (the Chairman) wished they could; for it meant £5000 a year more to the Company, as everybody thought "annual value" meant annual rent, and the Company charged accordingly. The Town Clerk argued that they agreed to "annual value" as defined by law. He (the Chairman) saw no such words in the agreement. Of course, they were bound by the law; and if the Corporation had thought that "annual value" meant annual rent, less rates and other charges, they would not have accepted the position of paying upon annual rent for so long a period. In their last report the Corporation were misleading the water consumers by stating that "annual value" meant rateable value. The Directors did not intend it to mean this. Another thing said against the Company was that they charged whatever they could get. In answer to this he would say that he did not know a single case where an incorrect charge had been pointed out to the officials and the mistake had not at once been rectified. In no instance was proof brought forward of a charge being in excess of the rental of the premises as given by the owner or occupier. The Directors did not want litigation; but they were not going to be driven to the rate-book to determine what was the meaning of "annual value." If they took it from the rate-book, they might have a case where "annual value" meant to them nothing at all. In conclusion, he expressed regret that the Bill had not passed, and added that the Directors were obliged to submit, and would submit with good grace. They did not wish to be in opposition to anybody; but they had a right to ask for just, and even generous treatment, considering they had saved the district thousands of pounds. If the Bill had passed, there would have been an annual saving equal to a capitalized sum of upwards of £3000; and the Company's customers would have been more satisfied than they were under the present arrangement.

Mr. TOWNSEND seconded the motion, which was agreed to.

Dividends for the half year, of 5 per cent. per annum on the preference and ordinary stock, and 4 per cent. per annum on the Dudley preference stock, were then declared; and the proceedings closed with a vote of thanks to the Directors.

SOUTH ESSEX WATER COMPANY.

The Ordinary Half-Yearly General Meeting of this Company was held at the Guildhall Tavern last Friday, Mr. W. CRACROFT FOOKS in the chair.

The SECRETARY (Mr. C. J. FOX) read the report of the Directors, which stated that the accounts for the half year ending June 30 last showed a net profit of £2037; being an increase of £218 on the profit of the preceding six months, and of £553 on that of the corresponding period of last year. During the half year 265 new services had been added, representing an addition of £285 to the annual revenue according to the present rating. After providing for interest, &c., the Directors recommended a dividend of 5 per cent. for the six months upon the preference stock, and one at the rate of 10 per cent. per annum upon the ordinary stock.

The CHAIRMAN, in moving the adoption of the report, said there were several reasons why it was not more satisfactory—the principal one being the lowering of rentals throughout the Company's district. But this was a temporary contingency which might be trusted to rectify itself; for while a depreciation in rents existed at present, it might result in a rise at any future time. The decrease in coal consumption, cost of repairs, and working expenses at Grays, noticed in previous reports, continued; and he fully anticipated a further decrease when the construction of the Aveley reservoir was accomplished. This was a project which had long been in contemplation; and, in view of the outlay on this head, the Directors proposed to issue further capital. The Company had lately been subjected to an adverse agitation in the Brentwood district; but he had no hesitation in saying that the outcry against them proceeded on a false basis, and that it would soon cease. As to the dividend, he hoped it would not merely be maintained, but prove to be progressive.

Mr. J. C. AMOS seconded the motion. He entered into details showing the advantages that would accrue to the Company from the construction of the Aveley reservoir; and spoke hopefully of their prospects.

After a few remarks from Mr. GODFREY, J.P., with reference to the Brentwood difficulty,

Mr. C. C. LEWIS, Coroner for South Essex, stated that personally he had no grievance against the Company, because he had been fairly met by the Directors. He knew, however, that owners of cottages at Brentwood did not at present receive enough out of them to pay the water-rates; and he suggested, as a *modus vivendi*, a conference between the Directors and the water consumers of the district.

Mr. C. C. S. FOOKS, jun., replying, on behalf of the Directors, to the various statements made during the discussion, pointed out, in regard to the water-rates being demanded in advance, that Mr. Forrest Fulton's Act practically compelled every water company to collect in advance, particularly in regard to small properties, which constituted the majority in this Company's district. There was an impression that at Brentwood and in the higher districts the supply was cut off at night. On the contrary, the supply was constant; only the pressure was reduced.

After some further discussion, the report was adopted, and the meeting closed with the usual vote of thanks to the Chairman.

PROPOSED ADOPTION OF GAS FOR PUBLIC LIGHTING AT RAWDON.—Up to the present time the township of Rawdon has not had the benefit of public lighting; and an agitation has been going on for some time with a view to secure the adoption of gas-lamps in the streets. The opinion of the members of the Local Board is divided on the question; and it was resolved to submit it to a ratepayer's meeting. This was done last Thursday, when Mr. T. Arton (Chairman of the Local Board) explained that it had been calculated that to light up a portion of the township which he indicated, placing the lamps 70 yards apart, 53 lamps would be required; but for a more extended area 104 lamps would be necessary. It was calculated that the lamps would cost about £2 10s. each, and probably about £1 each for gas and maintenance. It seemed to him that if they adopted this lighting scheme it would mean the addition of 4d. or 6d. in the pound to the rates. After some discussion, the project was rejected by 65 votes to 42. A poll is to be taken on the question.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

Considering their experience of the office they hold, the Gas Commissioners of Edinburgh and Leith are "putting their house in order" as speedily as is consistent with decorum. At nearly every one of their frequent meetings important appointments have been made, and other business (mostly of a formal nature) has been transacted, which affords a means of estimating how they are likely to carry on their undertaking. It must be a satisfaction to all who are interested that they have done so well in what they have already accomplished. To take the matter of appointments, there can be but one opinion—that the Commissioners have, in every instance, done the best they could in the interests of their constituents. It should not be lost sight of that gentlemen in their position are, on the occasion of making appointments, subjected to severe pressure on behalf of particular candidates, which makes it difficult for them to keep in view what should be their first consideration—the selection of the best man. The Commissioners have not escaped from this ordeal; indeed, it is freely stated that one of their own number had an eye to the "fleshpots" of office under the Commissioners, but was restrained from putting forward his "claims" by the knowledge that his colleagues were resolved to manage the gas supply for the benefit of the community, and not for the purpose of finding posts for all their needy friends. The appointment of Auditor at Monday's meeting brought out what had every appearance of being "interested" nominations; but they received scant support, and the Commissioners gave the post to the only man to whom they could with decency have offered it. Except on a score of personal friendship, one cannot conceive a reason for any Commissioner bringing forward an outsider when it was known that Mr. Wodrow Thomson was willing to undertake the duties. Mr. Demar's appointment to the post of Superintendent Surveyor was almost a matter of course; his claims, on account of his former status and his abilities, making it next to an impossibility to pass him over. All the principal appointments have now been made, with the exception of that of Engineer; and, in connection with this, it will be observed that the Commissioners on Monday "districted" the area of supply—dividing it as nearly as possible equally between the Managers of the two gas-works. Under this temporary arrangement, things may go on quite smoothly for a while, until the Commissioners are able to make up their mind on the subject. I presume the Commissioners are able to delay this matter because of the circumstance that—gas engineering being so much of a specialty—there are no outside applications for the post, and that consequently nothing can be lost to anyone by a little delay.

Mr. G. Livesey's award on the points which were in dispute between the Edinburgh and Leith Gas Commissioners and the Gas Companies was given promptly; Mr. Livesey having, as I anticipated a fortnight ago, no difficulty in the matter. His decision, whatever its effect may be, is founded on an exceedingly fair reading of the Act of Parliament. The expectation was that he would decide what description of implements did, and what did not, fall under the expressions "in use" and "in store or in hand." Instead of doing this, he adopted a course which enabled him to avoid giving, by precedent, a legal interpretation to the above words, and by which, also, the parties may quite as easily determine what is or is not to be paid for.

What underlay the stubborn resistance of the Companies was the desire, not to be paid for goods that were actually in use, but for such goods as meters returned owing to the caprice of customers, and which were actually "in store or on hand." The award is not inimical to this view, because if the Companies possess any such implements in excess of their maximum requirements, they will receive value for them. It is announced, through the channel of the Commissioners, that the Committee will save about £5000 by Mr. Livesey's method of settling the question. How much the Companies have gained—that is to say, how much more than £5000 the Commissioners expected to save—has not yet been ascertained.

I sometimes think that gas companies are subjected to more stupid treatment than any other of the quasi-public bodies that have extensive dealings with the community; though for what reason I can never satisfy myself. The question of way-leave for gas-mains has of late been exciting some interest in Fifeshire; and it was under consideration in the Pittenweem Town Council at a special meeting last Friday night. The local Gas Company propose to relay their mains, and are prepared, under an agreement entered into in 1845, to compensate the Police Commissioners for any damage they may do to the thoroughfares by their work. This appears not to have been good enough for the Commissioners; and they made a monstrously absurd demand that, instead of paying for surface damage, the Company should make an abatement of 25 per cent. upon their charge for the public lighting. Of course, the Company refused to agree to the proposal; and a letter to this effect was read at the meeting of the Council. The foolishness of the proposition comes out in this—that had the Company acceded to it, they would have escaped from the provisions of the agreement of 1845. They might then, with impunity, have done any amount of damage to the streets, and could not have been called upon to make it good. If the Commissioners wish for a reduction in the charge for public lighting, it should be made a matter of straightforward negotiation, and not be mixed up with other matters, particularly with those which, as in this instance, are already covered by perfectly safe agreements.

At the meeting on Monday of the Forfar Gas Corporation, the annual accounts were submitted by Mr. Craik. He said they showed that the consumption of gas had fallen short of the estimates by a million cubic feet, which was equivalent to £275 reduction in the revenue. Residual products exhibited an increase of £73; while, to meet the decrease, there was a corresponding saving on the other side of the account—viz., a reduction of £443 on the estimates for coal. In regard to the estimates, they showed that the price of gas could be reduced by 3d. per 1000 cubic feet. None of the Commissioners, he thought, would take credit for this reduction, because it was simply due to the lower price of coal. He moved that the estimates be approved, and that the price of gas be reduced to 4s. 4d. per 1000 cubic feet. The motion was unanimously carried.

The Gas Commissioners of the Aberdeen Town Council, in considering the question of the complaints furnished to them in writing by the "Agitation Committee," with reference to alleged overcharges in the gas accounts, have, it is said, found that of the 120 cases stated, some are not borne out by the books in the gas office; and a Committee has been appointed to thoroughly examine into the matter, and to report.

The Cupar Town Council seem in a fair way towards settling their difference with the local Gas Company in regard to the public lighting. The proposal of the Company is that the charges for gas should be regulated by the period in which the different classes of lamps are lit; the charges ranging from 8s. 6d. to 21s. 6d. per lamp. At present the prices range from 5s. 9d. to 18s.; and the increase, being so large, was resented—the Town Council threatening to charge way-leave for the use of the streets, if the increase was enforced. After negotiation, the parties have, so far, agreed on a basis of settlement in the following terms:—(1) That from and after Sept. 1, the lighting, extinguishing, cleaning, maintenance, and renewal of

the street lamps and lamp-posts be undertaken by the Company; (2) that the price to be paid by the Police Commissioners to the Company in respect of this undertaking be 7s. 6d. per lamp—the number of lamps to remain as at present; (3) that the burners used be Bray's "special;" (4) that this agreement subsist till Sept. 1, 1892, the Directors being unable to contract for a longer period, in respect that the contract of copartnership expires on May 1, 1893; (5) that the condition proposed by the Police Commissioners to reserve the right to charge a rent for the use of the streets by the Gas Company for laying their pipes, &c., cannot be entertained; (6) that a formal agreement embodying this arrangement be entered into, if required, by either party.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

A statement has been made public this week to the effect that the Glasgow Corporation Gas Committee are prepared to recommend the Town Council to purchase the works and goodwill of the Partick, Hillhead, and Maryhill Gas Company, Limited, for the sum of £170,000. I am not aware how such a sum has been fixed upon as the value of the undertaking which is such a powerful competitor throughout the western and north-western suburbs of the city, nor am I aware that any overtures have been made to the Glasgow Gas Trust for the sale of the works. It is not likely, however, that any purchase of the undertaking can be made in the meantime, however willing the two parties may be to come to an understanding on the subject. There is a possibility, however, that when the Glasgow Boundaries Extension Scheme is next promoted in Parliament, it may contain the necessary clauses providing for the purchase of the Partick Gas-Works. The prices of that Company's ordinary and preference shares are keeping very firm.

At the monthly meeting of the Greenock Police Board last Tuesday—Provost Shankland in the chair—a discussion took place as to whether there should be a reduction of 5d. or of 2½d. per 1000 cubic feet in the price of gas. The estimate for the current year, on the basis of the present rates, placed the revenue at £96,800; and the expenditure, including £5500 for interest and £8000 for the sinking fund, at £33,680—showing a surplus of £3120. Mr. McOnie, Convener of the Gas Committee, proposed that the reduction be 2½d. per 1000 cubic feet. This was seconded by Bailie Shearer; while Mr. J. Lang moved, and Mr. McInnes seconded, that the reduction be 5d. Mr. Mitchell moved that a Committee of Inquiry be appointed, with a view to a reduction. After some discussion, the Committee's proposition to reduce the rate by 2½d. per 1000 feet was carried by 14 votes to 8. The price is now 3s. 6½d. per 1000 cubic feet.

At the meeting of the Stirling Town Council on Monday, Treasurer Gray, the Convener of the Lighting Committee, reported that he had received a verbal offer from the Gas Company as to a proposed new arrangement for the public lighting. It was to the following effect:—That for lamps kept alight from sunset till one a.m., the charge would be 17s. 6d. each; for lamps kept alight from sunset till sunrise, 34s. each; the period of lighting to be from Aug. 15 till May 15, excepting moonlight nights; but if the lamps were required to be lighted on moonlight nights, the charge would be from 4s. to 4s. 6d. extra for each lamp. The charges mentioned were for No. 3 burners; but if No. 2 burners were used the charges of 17s. 6d., 34s., and 48s. would be reduced, respectively, to 1s. 6d., 3s., and 3s. 6d. The Gas Company would undertake to provide and maintain the lamps and posts, and to light and extinguish the lamps, and do everything in connection therewith, as at present, but without making any extra charge therefor. If the charge for gas to private consumers was afterwards increased or reduced, the Company would make an increase or a reduction on the charge for the three classes of lamps, respectively, of 3d., 7d., and 10d. per lamp for every 1d. per 1000 cubic feet of increase or decrease. The Lighting Committee had agreed to recommend the acceptance of the Company's offer. At the close of Treasurer Gray's statement, some discussion took place, and eventually the minutes were approved of, and further arrangements as to the lighting of the streets and the bargain with the Gas Company were left with the Committee.

Owing to the visit of the Queen to Glasgow and the West of Scotland this week, the local pig-iron market has been much unsettled; the holiday spirit having taken almost complete possession of the members of the iron "ring." Generally, the prices of warrants had been decidedly firm. Yesterday up to 40s. 6d. cash was paid for Scotch iron; business being done also in Cleveland markets at 33s. 10d. cash, and in hematite at 44s. 1d. cash. Some of the leading special brands have likewise advanced in price 6d. or 1s. per ton.

The local coal trade continues to show improvement from week to week; and prices are firming up in almost every department.

THE SOUTH LINCOLNSHIRE FEN WATER SCHEME.—The Long Sutton Local Board of Health had under consideration, on Saturday, the 18th inst., the Lincolnshire Fen water scheme, which proposes to supply water from a boring at Tongue End, near Spalding, to the towns and villages between Spalding, Holbeach, Long Sutton, and Sutton Bridge, and also to Crowland. Mr. Ffolkes, the Engineer to the new Company, attended the meeting at the request of the Board, and explained the scheme; pointing out that the Board could, if they thought proper, have the water in bulk, and then supply it to the inhabitants of the town and neighbourhood, which they would be enabled to do at a profit. He stated that the water which had been secured was excellent for drinking purposes, and also for use in boilers, breweries, &c. It was also calculated that the project would be of great benefit to agriculturists, and would save considerable expense and inconvenience which they were now put to in carting water for their stock and other purposes. It was further stated that no charge would be made for water used in extinguishing fires. A resolution was passed expressing the hope that the Company would speedily furnish a supply to the district.

THE PUBLIC LIGHTING OF YORK TOWN.—The adjourned meeting of the Lighting Inspectors of York Town took place on Friday, the 10th inst. The patentee of the Stringfellow lamp again attended, and stated his willingness to remove his lamps if they did not give satisfaction, immediately on receiving notice from the Board. Two members expressed their belief that arrangements might be made with the Gas Company; and it was resolved that a deputation should meet the Directors, and report the result at an adjourned meeting—the basis of reopening negotiations with the Directors being that they should waive their claim for £5 11s. 11d. The adjourned meeting of the Inspectors was held on the following Monday, when the deputation, who waited on the Directors the same evening, stated that they were willing to forego their claim, and to send in a tender; but would not again supply gas by meter. The deputation had, on behalf of the Inspectors, withdrawn the statement in their letter, "and declined any further correspondence on the subject," which appeared to have been a misunderstanding on both sides. The Directors offered to send the Inspectors a tender as soon as they had time to frame an estimate; and the Inspectors adjourned to await the receipt of the tender.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Aug. 25.

Sulphate of Ammonia.—The market, though apparently dull, preserves its steady tone; and prices are, if anything, a little firmer. At Hull, the principal business has been done at £11 8s. 9d.; although in some cases £11 7s. 6d. has been quoted. At Liverpool, there is a lack of supplies; and the parity of about £11 10s. is being accorded. The Leith quotation is £11 7s. 6d. to £11 8s. 9d. The lateness of the season, the unfavourable weather, and the consequent indifference of buyers, have been the cause of the great stagnation during August; and this being so contrary to precedent, it is just possible that we may see the revival later than usual, and that September may occupy the place usually usurped by August. The production will soon begin to increase again; but circumstances may contribute to fully maintain values. The nitrate market, especially for future delivery, continues very strong.

LONDON, Aug. 25.

Tar Products.—With the exception of anthracene, most of the products are dull and little inquired for. Pitch is remarkably weak; buyers declaring that they will not pay higher prices for it. Very little business has taken place during the week. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 2s. 10d. per gallon; 50 per cent., 2s. 4½d. per gallon. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate of ammonia continues flat, and although considerable shipments have been made to new ports, they have been more than counterbalanced by the absence of demand from the usual channel. The price is nominally the same. Sulphate of ammonia, £11 5s. to £11 7s. 6d. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Aug. 25.]

Sulphate of Ammonia.—At some of the ports sulphate of ammonia has experienced a further fall; but, strange to say, so good has been the demand at Liverpool, on account of Spanish and other orders, that the price at this port now equals that at Hull or Leith. This is quite unprecedented, especially as Beckton value is now only £11 7s. 6d. Hull and Leith are quoted at £11 7s. 6d. to £11 8s. 9d.; while London outside makes are value for £11 12s. 6d. The present state of the market is most abnormal; and it is difficult to account for it, except by the most unsatisfactory state of the weather and of the crops. Still the nitrate market keeps very firm.

Tar Products.—From several quarters we hear that benzols are a bit firmer, though the actual price has not sensibly advanced, at least so far as sellers are concerned. If quantities were required through second hand, there is no doubt an advance would be required, as there is but little free to offer; 2s. 4d. and 2s. 11d. were spoken of on Manchester "Change" last Tuesday, for 50 and 90 per cent. respectively, but we could not hear of any actual business at these prices. Crude carbolic acid remains in much the same condition as last week; while anthracene is, if anything, firmer, especially for "B" quality and qualities intermediate between good "A" and "B." Pitch remains at 13s. to 13s. 6d. at the port of shipment; but we understand it is being offered on the Continent at lower rates than these.

SALE OF SHARES.—At the Mart, Tokenhouse Yard, on Tuesday last, 15 fully-paid £10 shares in the Bromley (Kent) Gas Company were sold for £20 10s. each.

THE SEWAGE OF CAPE TOWN.—The Municipality of Cape Town have had considerable difficulty in dealing with the sewage of the city; and although the cost of the sewage disposal works must be of enormous magnitude, nothing yet appears to have been done to permanently remove the difficulties which at present exist. Numerous proposals have been considered; but finally the authorities have retained the services of Mr. E. Pritchard, M.Inst. C.E., of London and Birmingham, to make a personal inspection of the district, and prepare a comprehensive report thereon; and he has just left England for the Cape for this purpose.

THE NORTHERN COAL TRADE.—There has been increased animation in the coal trade of the North during the past few days, and the price has become decidedly firmer. Steam coal is about 7s. 6d. per ton; but one or two of the best collieries ask 7s. 9d. In the gas coal trade, the advance which we named last week has been obtained in one or two instances; and there seems a probability that it will become more general where contracts do not intervene. In the case of another colliery, the price has been fixed at 7s. 6d. per ton, less 5 per cent., so that it is evident the upward movement is becoming more common. A strike at the Murton and South Hetton Collieries is keeping some 2000 tons of gas coal daily out of the market; and this is giving owners of other collieries more chance of obtaining the higher price. House coal is very dull in demand, and weak in price.

SEVENOAKS GAS COMPANY.—At the half-yearly meeting of this Company held last Thursday, the Directors reported a steady increase in the consumption of gas, and a marked improvement in the value of residual products. The gross revenue for the half year was £4904 9s. 5d., as against £4388 18s. 5d. for the same period of last year. The total expenditure was £2866 6s., as compared with £2795 3s. 8d. last year. The amount available for dividend was £2133 10s. 9d.; and the Directors recommended the payment of 10 per cent. per annum on the original capital, and 7 per cent. per annum on the additional capital (both less income-tax). The price of gas has been reduced 2d. per 1000 cubic feet throughout the whole district supplied by the Company, which, it is hoped, will tend to still further encourage its use. The report was adopted; and the dividends recommended therein were declared.

THE WATER SUPPLY OF LIVERSEDGE.—At the last meeting of the Liversedge Local Board, Mr. J. Hurst gave notice that on the next occasion he intends to move that the Board enter into negotiations with the Corporation of Wakefield and the Local Board of Heckmondwike, with the view of obtaining the lowest price at which they would supply Liversedge with water under an agreement for a number of years; and also that the Board obtain Counsel's opinion as to the best course to take to get free from Bradford, whether by Provisional Order, by opposition to Bradford in the event of their going to Parliament for powers to construct new works, or by themselves promoting a Bill in Parliament for that purpose. A similar resolution was adopted by the Local Board last year; but on appeal to the ratepayers on the question of going to Parliament, the Board were defeated—from a misconception in the public mind, it is said, as to the meaning of a new proposal from the Bradford Corporation to supply the township on a fresh basis.

WORKING WATER AND GAS COMPANY.—In their report for the half year ended June 30 last, the Directors of this Company recommended an interim dividend at the rate of 3½ per cent. per annum.

THE PUBLIC LIGHTING AT FLEETWOOD.—On Monday evening last week a meeting of the ratepayers of Fleetwood was held to consider the subject of the price charged for gas in the town, and also the best means of improving the public lighting. Mr. T. Seed (Chairman of the Improvement Commissioners) presided. The first resolution submitted was to the effect that the price of gas ought to be greatly reduced; and this was carried unanimously. A Committee was then formed to make inquiries as to the methods of lighting adopted in other places, and the cost thereof, and to report to a subsequent meeting. A communication was read from the Public Streets Lighting Company offering to light the whole of the streets of Fleetwood with petroleum oil lamps, as now in use at East Moulsey and elsewhere. They also offered to supply, by way of experiment, some of the Company's lamps. A communication was also read from Messrs. Chamberlain and Hookam, Limited, with reference to the illumination by the electric light at Leamington, and inviting a deputation from Fleetwood to meet them at that place, and gather opinions as to this method of lighting both houses and streets. These communications were left to be dealt with by the Committee.

THE COST OF THE PROPOSED ELECTRIC LIGHTING AT CHELTENHAM.—Referring to a statement which appeared in the *Engineer*, to the effect that the Cheltenham authorities propose to light part of the town with 36 electric lamps in substitution for 170 gas-lamps, and that the cost of the electric light was to be £444, Mr. Denny Lane has written to that publication to point out that there is an error. He says: "The present cost of the 170 gas-lamps is £444, or £2 12s. 3d. per lamp, and the Committee suggest that the contractors who now supply 70 lamps to the Corporation of Bath at £18 17s. 6d. per lamp, should be asked to supply 36 lamps to Cheltenham at the same rate per lamp, which would amount to £679 10s., and not £444. I must remark that it is highly improbable that 36 lamps could be supplied at as low a rate as 70, since I believe there would be little difference in the skilled labour and attendance for either installation, which would have to be divided over only half the number of lamps at Cheltenham. I may add that it seems unfair to gas companies that corporations should have the power of contracting with them for only three years, while at Bath the contract for electricity extends to seven."

PROPOSED ELECTRIC LIGHTING AT RICHMOND.—At the meeting of the Richmond Select Vestry on the 14th inst., the Clerk read a letter from the Secretary of the Richmond Gas Company (Mr. E. B. Blott), acquainting the Vestry with the resolution come to by the Company to reduce the charge for the public lamps from £3 10s. to £3 6s. 8d. per lamp per annum, as from the 24th of June last. Notwithstanding this concession, the Vestry on the same occasion referred to the Parliamentary Bills Committee an offer from Mr. R. F. Coles, on behalf of the proposed Richmond Electric Lighting Company, Limited, to the following effect:—That in consideration of their transferring, or delegating to him, on behalf of the Company, the Provisional Order and powers held by the Vestry from the Board of Trade for electric lighting within their area, and giving him any necessary assistance to have their Order altered or substituted for similar powers under the new Act, and further guaranteeing him entire co-operation and support in the matter of electric lighting in their district, the Company would either pay him a royalty of 1s. per light per annum (street lamps by special contract), or if preferred would undertake to give a fixed sum—say, £150 per annum—for consideration of the transfer. He undertook to satisfy the Vestry as to the *bona fides* of the undertaking; and mentioned that he had orders in hand for some 200 lights, and only desired the sanction of the Vestry before commencing the erection of a central station.

CONSTANT v. INTERMITTENT WATER SUPPLY AT SHREWSBURY.—The Water Engineer of the Shrewsbury Corporation (Mr. W. Chapple Eddowes) has lately presented to the Water Committee a report giving the results of some trials of the constant as against the intermittent service on a portion of the district of supply. The tests extended over six days on each system; the number of houses being 600, and the population served about 3000. On the intermittent system the total consumption was 488,700 gallons; being an average of 81,450 gallons per day, and 27.75 gallons per head per day. On the constant system the total was 879,850 gallons; being a daily average of 146,641 gallons, and a consumption of 48.88 gallons per head per day. "This shows," Mr. Eddowes says, "an increase of 65,191 gallons on a constant supply of water. Over the whole borough, the consumption, based on the above increase per 3000, would equal 651,910 gallons per day above the average consumption per day for the year. To give a constant supply under the present circumstances, 651,910 gallons would have to be pumped in addition to the average quantity per day, simply to run to waste. The cost for fuel alone to raise this additional quantity would be not less than £500 per annum. This would be a very extravagant sum to pay for pumping water to run to waste," owing to the defective condition of the fittings in the houses, to which he had previously called the attention of the Committee. The great leakage which has been going on in the city has led to a trial of Deacon's meters; and the Borough Surveyor has reported favourably thereon.

IMPROVED STREET LIGHTING IN ST. JAMES'S.—The report for the parish of St. James, Westminster, for the twelve months ending March 25 last, which has just been published, states that the demand for better lighting in different parts of the parish engaged the attention of the Vestry on many occasions during the year. On March 25, 1887, there were in the various thoroughfares of the parish 771 public lamps, 744 of which were ordinary street lamps—458 burning candle and 286 ordinary gas. In March, 1888, the number of lamps was 778; and the contract sum paid to The Gaslight and Coke Company for lighting, extinguishing, cleaning, and maintenance was £2 7s. 7d. per lamp yearly—the gas burned being 2½ cubic feet of candle and 3 cubic feet of common gas per hour. The total cost of street lighting was £2325 10s. 6d. for the year, against £2433 12s. 9d. in the previous twelve months. In February last the Vestry took into consideration the question of improved lighting. Taking advantage of a large reduction in the price of gas, they determined to increase the consumption in the street lamps generally, and thus practically place all streets on the same basis as regards lighting. Two years previously, the consumption of gas in the Regent Street lamps had been increased from 2½ to 4 cubic feet of candle gas per lamp per hour; and this improvement was so marked that this rate of consumption has been adopted for the streets generally. The number of street lamps has been altered to 582. The increased cost is only £371, from which a small sum saved in respect to the refuge lamps is deducted—leaving the net increase only £347. The light in the street lamps has been increased 60 per cent.; and the extra cost to the ratepayers was less than half a farthing in the pound. The Vestry do not appear inclined to remain satisfied with this improvement, seeing that there are even now defective and obsolete lamps in some of the leading thoroughfares, such as in Piccadilly, where heavily-metalled old-fashioned lamps still exist to obscure a fair proportion of the light. Many lamps of this description will require to be replaced at no very distant date.

BELFAST WATER SUPPLY.—It is satisfactory to learn that all danger of the recurrence of a short water supply in Belfast has been removed. The immense culvert of seven miles in length, connecting Stonyford with the Lagmore reservoir, the construction of which was entrusted to Messrs. Fitzpatrick Bros., of Belfast, has been completed, so that the present town supply can be supplemented at any moment should necessity arise. The Water Commissioners laid a section of the pipes; and on the 11th inst. Messrs. Fitzpatrick announced the completion of their portion of the contract, on which the utility of the Commissioners' work depends.

HARTLEPOOL GAS AND WATER COMPANY.—The report of the Directors of this Company has been issued to the shareholders, together with the balance-sheet for the year ending June 30 last. The latter shows a considerable increase in the consumption of both gas and water during the past year; and there is every prospect of a further increase during the ensuing year. There is also a slight improvement in the value of residuals. The balance available for division is £11,154 14s. 9d., out of which the Directors recommend the payment of a dividend for the past half year at the rate of 6 per cent. per annum upon the whole of the paid-up capital of the Company, less income-tax; leaving a balance of about £2976 to be carried to the next accounts. The new offices have been completed, and meet the contemplated requirements. The new pumping-engine at the water-works, capable of raising 150,000 gallons of water per hour, has also been finished, and is working satisfactorily. Sulphate of ammonia works are in course of erection, and will be ready to commence operations this autumn.

CANTERBURY GAS AND WATER COMPANY.—The Directors of this Company, in the report which they will present at the forthcoming half-yearly meeting of shareholders, state that a year's experience has shown the correctness of the calculations they made when the reduction in the price of gas was determined on. The large gasholder erected from the plans of Mr. H. E. Jones, M. Inst. C.E., has been fully tested, and is now in satisfactory working order. This new and valuable portion of the gas plant has been erected at a very moderate cost—the total expenditure on the work, including the Engineer's commission, being £4899 18s. 5d.; and this sum has been duly paid out of the loan capital recently raised. In the Water Department no capital expenditure has been required during the half year beyond a small outlay on the extension of mains to new property; and the works are all in efficient order and good repair. The balance standing to the credit of the profit and loss account is £5908 11s. 2d.; and the Directors therefore recommend that the usual dividend after the rate of 8 per cent. per annum for the half year be declared and paid free of income-tax, and the balance carried forward.

† Next dividend will be at this rate.

Acts of Parliament regulating their undertaking. Over and over again, however, it has been shown by the Superior Courts that these conditions do not bind the passenger if they are unjust and oppressive. Again, contract or no contract, the Legislature absolves by special enactment incoming tenants from liability for the arrears of their predecessors; and it is not a great stretch to imagine that it might be moved to relieve outgoing tenants from the debts of their successors. The incident has an unpleasant look; and it is to be regretted that the Company come out of it under such a harsh aspect. We would not absolve a consumer from the duty of applying for a supply of gas in his own name, nor from duly giving notice of his intention to terminate a tenancy. The temptation to do as Mrs. Darbyshire says she did—to transfer the use of the meter to the incoming tenant, for his convenience, and to avoid an interregnum of darkness and the expense of reconnecting the supply—is, however, very great; and some forbearance is due to those who yield to it, to the sacrifice of strict legal forms. The question as to whether any notice was really given by the Darbyshires, and acted upon by the Company, remains unsettled. They swore that it was so; and against these asseverations there is nothing but the denial, unsupported in any way, of Mr. Arthur Dove for the Company. Surely, if the Company did send a man as asserted, some entry in a book would record the fact; and this could have been called for. The whole case has an unfinished as well as the hard look already remarked; and by no possible way of examining it can satisfaction be drawn from it.

A LOCAL BOARD CONVERTED INTO A GAS COMPANY.

STUDENTS of precedents in Gas Legislation should procure a copy of the Nelson Local Board Act of the past session, in which they will find a remarkable compact between the Board and one of their neighbours, the Brierfield Local Board. It is enacted that, as between the two Boards, the Nelson Local Board, who own the gas-works supplying the two districts, are not to make a greater yearly profit out of their undertaking than 10 per cent. upon not more than £65,000, and 7 per cent. upon the remainder up to £100,000; such capital being actually expended at the time for gas-works purposes. No deduction is to be made for any part of this amount which may be repaid by the operation of the sinking-fund; but the Brierfield Board district is not to be called upon to find, or to be debited with, any such sinking-fund payments. The term profit is not to include any allowance for depreciation; and section 35 of the Gas-Works Clauses Act, 1847, is amended by substituting the name of the Brierfield Local Board for the two gas ratepayers who are empowered under that section to move the Court to inquire into the condition of the undertaking in which they are interested. This means that the one Local Board will be served with gas by the other Local Board precisely as though the latter were a Gas Company working under the powers and provisions of the 1847 Act. The owners of the works are to charge a price for gas in the neighbouring district that will enable them to earn not more than 10 per cent. and 7 per cent. profits upon their original and additional capitals; and the Local Board which represent these foreign consumers are empowered to look after the supplying Board, just as though the latter were a Gas Company. This is another and a very striking example of the movement in favour of putting gas-supplying local authorities upon the footing of Gas Companies; and it deserves to be borne in mind. It is remarkable how these precedents seem to be slipped into Bills year after year without notice to anybody except the parties immediately concerned; and yet they are serious enough to give a colour to the whole course of legislation of the order in which they fall. It was the Oldham Corporation; now it is the Nelson Local Board. Who shall say what is to be the next example of the modern tendency to invest gas-owning local authorities with the attributes of Gas Companies?

PRIOR to leaving Manchester in order to take up his appointment of Engineer and Manager of the Nottingham Corporation Gas Department, Mr. W. R. Chester entertained to a farewell supper the members of the Mutual Aid Society, as well as the foremen, and others connected with the Bradford Road Gas-Works of the Manchester Corporation. The gathering was presided over by the Chairman of Mr. Chester's own Sub-Committee (Mr. John Hinchliffe), supported by Mr. Chesters-Thompson, Mr. Charles Nickson (Superintendent of the Gas Department), the Rev. A. Schofield, and Mr. Harrison. All these gentlemen addressed the gathering; and high appreciation was expressed of Mr. Chester's services and character, and regret that he was leaving Manchester.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 432.)

LIMITED business has again been the rule on the Stock Exchange, as might be expected; but the tone was better than in the preceding week. The slight degree of anxiety then produced by Continental affairs has apparently passed off, to the benefit of the Foreign Market; and the principal departments in general have had a favourable tendency. The Money Market remains about the same. Gas securities have been moderately active, considering the time of year; and all descriptions have been very firm. Important changes will be noted in the quotations; Gaslight and Coke, Brentford, and South Metropolitan being now quoted *ex div.* In all three cases, the variations show more or less of an advance in prices. Gaslight "A" was in good demand, and was done as high as 263 *cum div.* and 258 *ex div.*; but the latest marks were rather easier. South Metropolitans were almost untouched; a solitary deal in the "B" being all the business done. Confirming the opinion we expressed some little time ago, that the first half of 1888 would prove a good one for many Gas Companies (Metropolitan and others), two recent items of intelligence are of interest. The Directors of the Commercial Company announce that they will recommend an increase of $\frac{1}{2}$ per cent. in the next dividend; making 13 $\frac{3}{4}$ on the old stock, and 10 $\frac{3}{4}$ on the new. This is the full statutory rate permissible with the present price of their gas. We believe the Company have had a very successful half year, and will be able to carry forward a considerable balance after paying the dividend. The other item is furnished by the accounts of the Crystal Palace Gas Company, who appear to have earned their dividend and about £3000 more. They announce a further reduction in price to 2s. 8d. per 1000 cubic feet—the policy of which we are somewhat at a loss to understand. They are not expected to be able to undersell the big Company; they cannot increase their dividend; and they are giving away something that would be valuable hereafter, if they ever change their condition. Of the Foreign undertakings, Continental Union has been in best demand, and shows a slight improvement. Water has been quiet, but is very firm. The only change is a rise of 2 in Chelsea.

The daily operations were: Monday was about the busiest day of the week, especially for Gaslight "A," which rose 2, and Continental Union. In Water, New River debentures were done at 126 $\frac{1}{2}$. Tuesday was quiet; but prices were excellent. Commercial new and Chicago advanced 2 each; and Continental Union, $\frac{1}{2}$. Chelsea Water also rose 2. On Wednesday, hardly anything was touched but Gaslight "A," which was very firm. Quotations were made *ex div.*, the details of which will be found in the list at page 432. Gaslight "A," however, was quoted 1 higher; but on Thursday it was put back to 253-57. Water was quite stagnant. On Friday, Gas was extremely inactive, and presented nothing to notice. Water, however, did more business. Saturday was quiet as usual; and Gas transactions were very moderate, but at good prices. Commercial rose, on the announcement of the dividend—the old stock improving 2; the new, 1; and debentures, 3. Water was an absolute blank.

ELECTRIC LIGHTING MEMORANDA.

A MUNICIPAL ELECTRIC LIGHTING STATION FOR PARIS—THE TROUBLES OF THE PILSEN-JOEL COMPANY—RULES FOR THE ELECTRICAL FITTING OF HOUSES—A GERMAN ESTIMATE OF THE COST OF ELECTRIC LIGHTS.

IT is reported that the Municipality of Paris are really about to make a beginning in respect of electric lighting. As contractors have not come forward to compete for the concessions for lighting different parts of the capital by electricity, according to the scheme mentioned several times in this column, the Municipal Council have determined to make a start on their own account, in the district of the Halles Centrales. The details of this venture have been "studied" since March; and at last the Lighting Committee have plucked up courage to recommend the Council to proceed with the scheme. The plans have been drawn up by the City Engineers; and the total estimate for the work amounts to £40,000. When the tenders are received, they are to be examined by a Special Commission to be appointed by decree of the Prefect of the Seine. Thus in Republican France the popular governing assembly is not allowed to go too far. They are permitted to talk as much as they please, and even to instruct their scientific advisers to make plans; but the last word rests with the representative of the central power, just as it did in the darkest days of the defunct Empire. The price at which the Council think they will be able to supply current to their subscribers in the Halles district is 1s. 3d. per Board of Trade unit, which is equivalent to gas at 12s. 6d. per 1000 cubic feet. Before selling electricity by meter, however, the meter must be found; and accordingly the Council have opened a prize competition for electric meters—offering £800 altogether in prizes. Of this amount £400 is to go to the designer of a really perfect and satisfactory meter; and the rest, in sums of £80, is to be divided among the five next best. The prospect of this reward should stimulate makers of those instruments which Dr. Hopkinson told a House of Commons Committee were perfect in 1882, but which nobody believes in to-day, to bring out something really workable. The competing instruments will be examined by a Special Commission of nine members, who will adjudicate upon them, and award the prizes.

There is trouble in store for the Pilsen-Joel Company. Last

June a Committee of four of the principal shareholders, of whom Mr. J. E. A. Gwynne was one and Mr. Fyfe another, was appointed by the Company in general meeting to advise with the Directors as to the best means of disposing of the Company's business. Very recently Mr. Gwynne made an offer, which was accepted by the Board, to buy the concern right out for £4550, with a view to the formation of another Company to carry it on; and the shareholders have been invited to exchange their shares for shares of the new Company. Suddenly, however, Mr. Fyfe appears upon the scene, denouncing the transaction between Mr. Gwynne and the Board as fraudulent, and applies to the Court for an interim injunction to restrain these parties from carrying their agreement into effect. In this he has succeeded; and the matter will come before the Chancery Division in due course. As our contemporary *Money* remarks, these Electric Light Companies cannot keep out of Court. What their shareholders and promoters have spent in lawyers' fees and Court charges must amount to an enormous sum. If they cannot find money enough for embarking in legitimate enterprises, they can always rake enough together for litigation.

The London Electric Supply Corporation have issued a code of rules to be observed by electrical fitters in connection with the wiring of houses intended to be supplied with current by the Corporation. There is nothing like beginning as one means to go on; and if the Corporation should in the fulness of time succeed in making anything like a business, it will be useful to have a good body of regulations to fall back upon when fitters try to scamp their work. It would have been a good thing for gas consumers if gas companies in general had been entrusted with the power of inspection over internal fittings; so that they could have insisted upon the use of pipes of proper dimensions and strength. These rules for electrical fittings appear to be reasonable enough. The instructions respecting the size and method of insulating and protecting internal conductors seem well conceived for the objects desired, which are to ensure good work, and to avoid fires. Finally, the Corporation reserve the right of refusal to supply current to any installation before testing and satisfying themselves respecting the insulation resistance of the circuits. All this sounds very respectable; and it only now remains to put the rules in operation.

Papers on the cost of distributing electricity for lighting purposes from a central station have recently been published in the *Electrical Review* by Mr. W. Fritsche, of the firm of Fritsche and Pischon, of Berlin. In these papers the data relating to the consumption of current for different times of the year, and also those relating to the working expenses of an electric lighting station, are very carefully computed and plotted graphically in a series of diagrams that look as if they ought to be useful. Reckoning upon the basis of an average year of 1433·72 lighting hours, the author states that with 16-candle incandescent lamps, paid for at the rate of 4 pfennige (0·04 shilling) per hour, a station such as he has in his mind ought to pay 11·23 per cent. profit after allowing 4 per cent. interest on the cost of the plant, and providing for depreciation of machinery. This is rather under a halfpenny per lamp per hour, which is a price that several English electricians have already talked about as a satisfactory one for electrical undertakers. Mr. Fritsche, like most other Continental Engineers, works out his calculations with great precision to two or three places of decimals, which gives his results a look of extreme exactitude. This is quite illusory, however, because when one investigates these computations, they are found to rest upon several estimated factors which must be more or less variable, and any alteration in which would play havoc not only with the decimals, but also with the whole numbers of the result. Therefore Mr. Fritsche's precision is really of no more value than a very much rougher estimate, which might point to the same result without attempting to go so deeply into the data of lighting hours and working expenses. It has been abundantly asserted that incandescent electric lighting ought to be supplied at a profit from a central lighting station at a charge of one halfpenny per hour for a 16-candle incandescent lamp. This is equivalent to gas at about 8s. 4d. per 1000 cubic feet, and is probably the best that electricians can do at the present time. It leaves out of account, of course, the practical difficulty of carrying on a lighting business on a rental basis instead of on the meter system. Mr. Fritsche does not mention the use of consumers' meters, from which we judge that he does not think any device of this kind that has come under his notice worth serious consideration.

GAS LIGHTING AND PICTURE GALLERIES.

THE action of light upon painting is a subject which has exercised the minds of painters and their patrons since the time of the *Renaissance*; but it has been until comparatively late years mixed up with other considerations affecting the permanence of works of art in colours, such as the durability of varnishes. The effect of light in discharging the tints of pigments seems to have first become prominent as a question of distinct interest and importance in connection with the work of Sir Joshua Reynolds, who was an inveterate experimentalist in the matter of colours; and, to the sorrow and loss of posterity, sometimes confided the fruits of his genius as a painter to fleeting mixtures, the originally brilliant tones of which have vanished with time. Since this unfortunate experience, which has been repeated more or less in the case of other masters, painters have been very shy of unknown chemical mixtures of pigments, and have been cautious respecting the preparation of their canvases and the purity of the media with which their pictures are finished. The essentially British art of painting

in water colours, which is of modern growth, has always been specially liable to the kind of troubles referred to, on account of the thinness of the washes of colour laid on the paper, the variations of composition met with in the paper itself, and the absence of any protecting varnish from the finished pictures. Fears for the permanence of the colours have consequently oppressed the owners of collections of this class of pictures; and they have even suffered in value, in the commercial sense, from the prevalence of the idea that they do not constitute such a safe investment as oil paintings, which are known to improve with age. Many years ago the nation became possessed of a magnificent gallery of water colours, which has since been shown at South Kensington not only by day, but also by artificial light; and ever since there has been entertained in some quarters a rooted opinion, frequently expressed in Parliament and in the writings of art critics, that this constant exposure to light would, in the end, spoil the pictures. These observations had their effect upon the responsible authorities; and in April, 1886, the Lords of the Committee of Council on Education requested Dr. Russell, F.R.S., and Captain Abney, R.E., F.R.S., in order to settle the question by an exhaustive series of experiments upon the action of light on water-colour drawings. When this action was publicly heard of, the Royal Society of Painters in Water Colours very naturally formed the opinion that the advice of a water colour painter ought to be taken in respect of the conduct of these experiments, and made a representation to this effect, which was immediately attended to by their Lordships of the Committee of Council. Nine distinguished artists were accordingly added to the Experimental Committee in an advisory capacity; and they materially assisted Dr. Russell and Captain Abney collectively and individually. The result of the investigation thus set on foot has been published as a Blue Book, which contains a mass of most valuable information upon the different matters taken into cognizance by the Committee. Much of the contents of the book will be particularly interesting to students of water-colour painting, from the remarks upon the selection of colours by eminent living artists; while students of the science of light will find a great deal in it to instruct them respecting the modern theory of colour. With these portions of the book, however, we have here nothing to do. Our interest in the inquiry is confined to the practical aspect of the question of lighting; seeing that the subject of the suitability of gas for illuminating picture galleries is a matter of interest in other places than South Kensington, and this report constitutes the most authoritative treatment of the question that has yet been given to the world.

The first part of the report gives a comparison of sunlight with the lights of the electric arc and of a gas-flame, which were the artificial sources of light selected for investigation, as they are both used at South Kensington. It is remarked, upon the appearance of colours by these different means of lighting, that "no matter what the source of light may be—whether the yellowish-white light of gas, the purer white of the electric arc light, or of the sun, or the bluer white light from the sky—the comparative measures of the brightness of the different colours reflected from the two surfaces (white and coloured surfaces experimented upon with the spectrum) will always be the same To see what will be the colour of a pigment by gas light, the rays of the spectrum of gas light must be reduced in the proper proportion found for the particular pigment, and be again recombined; and this will give the colour of the pigment seen by gas light." Diagrams are given showing the three lights compared in various ways; and the effect of that portion of the total energy of the light which does not appear as visible luminosity is discussed. It is concluded that all lights are identical in effect, though they differ in intensity and in composition as shown by these spectra; consequently it is possible to deduce the effect of one from observations made upon any other which may be most convenient for experimental purposes.

In determining the question of the effect produced on pictures or anything else by the means adopted for lighting, it is, of course, necessary to ascertain its actual or relative intensity. Accordingly, in this case General Festing measured with the Preece photometer for diffused light the amount of illumination of some of the walls of the South Kensington picture galleries lighted by gas and other means. He found that, in the rooms illuminated by gas, the intensity of the light actually falling on the pictures ranged from 1·81 to 2·32 candles at 1 foot distance. The room lighted with incandescent electric lamps received light equal to that of 1·72 candles at 1 foot distance; and those lighted with electric arc lamps showed an intensity of illumination comparable to that of from 2·26 to 3·12 candles at 1 foot distance. It is remarked that the incandescent electric lamps and the gas gave light nearly of the same composition; so that the mean illumination of the pictures lighted by these sources may be taken, on the average, as equal to the light of 2 candles at 1 foot distance. This, it may be observed, is a very fair degree of intensity for artificial lighting. The mean daylight illumination in the same rooms is taken as about 6 candles at 1 foot distance all the year round. Taking the difference in the composition of daylight and gaslight into account, it is calculated that one hour's exposure to mean daylight is equal in effect to 45 hours of gaslight. As it is estimated that 100 years of exposure to this degree of daylight would have been required to produce the fading effect observed on certain experimental tints prepared for the purpose by the Committee and exposed to direct sunlight for many months, allowing for the duration of darkness, it would have taken at least 2000 years' continuous illumination to have produced the same result in gas light or in the light from the incandescent electric lamps. With the arc lights, giving an

average illumination of $2\frac{1}{2}$ candles at 1 foot distance, the Committee calculate, on similar data, that the same result would have been obtained in not less than 200 years. After this rate owners and custodians of private and public picture galleries need not fear the effects of any reasonable amount of artificial lights, especially if they eschew the electric arc in any shape.

Of course, to complete the information conveyed in the preceding paragraph, it is necessary to know the standard of fading taken into the calculations of the Committee; and this is only to be obtained by following all their observations upon the various experimental tints employed in their experiments, for which reference must be made to the voluminous tables given in the Blue Book. A question which many people will be apt to ask—as to whether the products of combustion of gas have any effect upon colours exposed to them, in addition to the light of the flames—has been anticipated by the Committee, who instituted an interesting experiment to settle it. An ordinary gas-jet, consuming 2 cubic feet of gas per hour, was kept burning day and night for three weeks in a cupboard 6 ft. 6 in. long, 2 ft. 6 in. wide, and 5 ft. 6 in. high. At the top of the cupboard was fastened a board, on which strips of different colours were pinned. The temperature to which the colours in this gas-stove were exposed was 82° Fahr.; and the cupboard window was consequently bedewed with moisture. “Yet, under these trying conditions, hardly any change occurred. Crimson lake was slightly bleached, madder lake became a little redder; and Antwerp blue and Prussian blue a shade greener.” Generally the Committee conclude that mineral colours are far more stable than vegetable colours; and that artists have a wide choice of pigments which may be regarded as permanent under all ordinary conditions of lighting, especially if moisture as well as fresh oxygen are excluded as completely as possible. The experiments go to show that the rays which produce by far the greatest change in a pigment are the blue and violet components of white light, and that these, for equal illumination, predominate in light from the sky; whilst (quoting from the report) they are less in sunlight and in diffused cloud light, “and are present in comparatively small proportion in the artificial lights usually employed in lighting a room or gallery. The experiments have also shown that about a century of exposure would have to be given to water-colour drawings in galleries lighted as are those at South Kensington before any very marked deterioration would be visible in them, if painted with any but the most fugitive colours; and that when the illumination is of the same quality as that of gaslight, or of the electric glow light rendered normally incandescent, and of the same intensity as that employed in these galleries, an exposure to be reckoned by thousands of years would have to be given to produce the same results. We have here not taken into account the action, if any, which might arise from the products of combustion when gas is the illuminant, and which our experiments so far have shown to have but a trifling effect.”

It will be gathered from this expression of opinion, which is entirely satisfactory so far as it goes, that while the Committee do not explicitly condemn the use of electric arc lamps for lighting picture galleries containing water colour paintings, they do not think them so harmless as gas or incandescent electric lamps; and also that they have not quite made up their minds respecting the actual effects of the products of combustion of coal gas. As this latter is a matter that efficient ventilation is competent to place out of consideration, it need not trouble owners of gas-lighted picture galleries where this prime requisite is provided. It may be remarked, among the many incidental points of interest ascertained or verified by the labours of the Committee, that the illuminating power of direct sunlight on a surface held normally to the direction of the beam on May 21 near midday was found to be equivalent to 5480 candles at a distance of 1 foot. With this extract we must terminate our notice of this work of Dr. Russell and Captain Abney; only adding by way of comment that, in thoroughness of execution and lucidity of explanation, it redounds to the credit of these accomplished experimentalists. If their work is defective at all, it is in the very obvious point that they could not determine the probability of fading in actual pictures by experiments with specially prepared tints which may not be of the same pigments as were employed by the older masters of water colour painting, in the permanence of whose works the nation is most particularly interested. This aspect of the question has been made the most of in a letter of Mr. J. C. Robinson, published in *The Times*, who advocates the framing of all such paintings *in vacuo* for the benefit of posterity; this being the device recommended by the Committee for protecting paintings in fugitive colours from the bleaching effect of oxygen and moisture. This is a matter for custodians of picture galleries to look carefully into.

The Secretary of the Commercial Gas Company (Mr. H. D. Ellis) informs us that, at a Board-meeting held last Friday, it was resolved that the dividends to be recommended for the past half year shall be at the rates of $13\frac{1}{4}$ per cent. on the old stock, and $10\frac{1}{2}$ per cent. on the new stock of the Company.

The Salford Town Council held a special meeting last Friday, to consider the position of affairs with regard to the Town Clerk. It was stated that £777 was due from Mr. Graves to the Corporation, £25 of which was received for attendance in London to produce certain Corporation books and documents at the trial of the late Gas Engineer. The Council dismissed Mr. Graves from office; and authorized steps to be taken for the recovery of the amount due.

Notes.

A NEW AIR PYROMETER.

At the meeting of the Iron and Steel Institute in Edinburgh last month, Professor Wiborgh, of the School of Mines, Stockholm, gave an interesting description of a new air pyrometer, specially designed for ascertaining very high degrees of heat. He claimed for it that, as compared with measurers of temperature of the same sort that have hitherto been used, it is of simpler construction, and can be handled by an ordinary workman. It gives as great a result for a certain difference of temperature, whether the temperature itself is high or low. The determinations of temperature can be made very rapidly, but yet with great nicety. The ball of the thermometer is not exposed to any difference of pressure outwardly or inwardly, other than during those moments when the observations of temperature are made. Lastly, the pyrometer, without further attention, is ready at any moment for readings of temperature; all these being qualities which should go far towards fulfilling the purpose for which it has been constructed—viz., of being a practical pyrometer for industrial purposes.

SOFTENING WATER BY LIME AND SODA.

Herr Otto Binder has devised the following method for determining the quantities of lime and soda required for softening water:—To 200 c.c. of water placed in a 300 c.c. flask are added 50 to 75 c.c. of saturated lime water containing a known proportion of lime. This is determined with a sulphuric acid containing, per litre, 1.85 grammes of sulphuric acid; 1 c.c. of the acid representing about 1 c.c. of lime water. It is prepared by diluting 46.43 c.c. of normal acid to 1 litre. The sample, mixed with lime water, is heated (the mouth of the flask being loosely stoppered with a perforated cork holding a thermometer) to the temperature designed for the softening of the water on the large scale; therefore to about 50° to 80° . When the contents are cold, the flask is filled to the mark with distilled water free from carbon dioxide; and 250 c.c. are filtered through a dry folded filter. In the filtrate the excess of caustic lime is titrated back; the quantity used for 1 litre being found by calculation. In most cases a considerably larger quantity of lime is required than that which corresponds to the temporary hardness. For the determination of the soda to be added, 250 to 300 c.c. of water is evaporated in a platinum dish to dryness with 5 c.c. of a normal soda solution. The residue is dissolved in water, filtered, washed, and the undecomposed sodium carbonate determined volumetrically with acid and methyl orange. The difference shows the proportion of soda needed for the decomposition of the chloride, sulphates, and nitrates. About 10 grammes of soda per cubic metre should be used beyond the quantity thus determined.

THE VALUE OF OIL AS FUEL.

In the course of a lecture delivered by Dr. Charles B. Dudley before the Franklin Institute, he made a comparison between the fuel values of petroleum and of different varieties of coal. For this purpose the composition of the oil was assumed to be 85 per cent. of carbon (by weight) and 14 per cent. of hydrogen. Anthracite coal was supposed to contain 90 per cent. of carbon; and bituminous coal was credited with containing 85 per cent. of carbon and 5 per cent. of hydrogen. Calculated upon this basis, 1 lb. of the oil was shown to be theoretically equal to 1.61 lbs. of the anthracite, and to 1.37 lbs. of the bituminous coal. Mr. Urquhart compares oil with coal as 1 to 1.756; and this valuation is confirmed by experiments at Detroit and upon the New York elevated railroad, all of which go to show that in round numbers 1 lb. of oil is capable of doing the work in the boiler furnace of $1\frac{3}{4}$ lbs. of the very best coal. Considering that oil is generally bought by the gallon or barrel, and coal by the ton—which, however, he takes at only 2000 lbs.—Dr. Dudley publishes in the *Journal of the Franklin Institute* some tables in which the relative values of the two kinds of fuel are balanced, both with reference to fuel account alone and also taking all ascertained economies into the computation. Upon the simple fuel basis, it appears that oil costing \$1 per barrel of 42 gallons is equal in value to coal at \$3.73 per ton of 2000 lbs. With all ascertained economies considered, \$1 worth of oil—42 gallons—is equal to \$3.26 worth of coal. Although oil is very convenient for steam raising, for many reasons it is not much used for this purpose in the United States, simply because at present prices it is more costly to obtain a stated amount of heat from oil than from coal. Even in Pennsylvania, with oil at 30c. per barrel, it cost nearly 50 per cent. more to move a train 100 miles by means of oil than when burning coal. Another potent reason why oil cannot replace coal for steam-raising purposes is that there is not enough of it, even in Pennsylvania. The only region where petroleum can supply the place of coal to advantage is that wherein the Russian product can be distributed at a low price, because the yield of the Baku wells is so large that an extensive consumption of the product for fuel would not affect the price, as in America.

BURNING GAS UNDER STEAM-BOILERS.

Natural gas is utilized for steam raising at Toledo, Ohio, and other places, in accordance with more or less well-imagined arrangements; the latest, and perhaps the best, being described and illustrated in a recent issue of the *Scientific American*. The boiler, a tubular one, is set in the usual manner. A set of grate bars are disposed over the ash-pit; their inner ends being inclined upward, and resting against the back furnace wall. Upon the top of the bars is laid a sheet of iron, which is also turned up at the back, so as to cover about three parts of the height of the inclined

portion of the bars. Upon this sheet of iron is placed a layer of fire-clay; and on this is laid, longitudinally with the fire-bars, a series of fire-clay pipes 6 inches diameter, and placed close enough to touch. Over the inner ends of these pipes is built a fire-brick wall, which leaves a space of about 20 inches between it and the back furnace wall; the tops of the two walls being covered by an iron plate. The supply of fuel gas is from the front, where a rising pipe brings the gas to a horizontal cross pipe ranged to a level with, and opposite the ends of the 6-inch fire-clay pipes already mentioned. This cross pipe is perforated with holes directly opposite to the centres of the fire-clay pipes. In operation, air enters the furnace underneath the fire-bars, and passes to the back, where it rises in front of the back furnace wall, and is then compelled to return to the front through the fire-clay pipes, where it supports the combustion of the gas. As the whole heat of the flame of the gas passes back over the top of the fire-clay pipes, they get intensely hot; and this combustion is therefore kept up with practically red-hot air. The arrangement is described as being very simple and highly effective, and is said to be coming into extensive use.

Communicated Articles.

GAS ANALYSIS.

By WILLIAM G. HICKS, Assistant Engineer of the Ramsgate Corporation Gas-Works.

I feel sure that no excuse is needed for writing on the subject of gas analysis. Everyone connected with gas engineering is fully aware of the importance of practical chemistry in investigating the processes involved in the manufacture of coal gas. The description of the apparatus used by me will therefore I hope be of interest to readers of the JOURNAL.

Description of the Gas-Bottle and Apparatus Attached.

The bottle B holds a litre of gas at 60° Fahr. and 30 inches bar. It is graduated on the neck from zero to 25 per cent., or 250 c.c. Each per cent. is divided into five parts; each part being equal to 2 c.c. In order to protect it as much as possible from external influences, the bottle is surrounded by a glass casing C, which is kept in position by india-rubber pieces D E, and made air and

water tight by a sheet india-rubber cap, stretched over the top at F. It is provided with a flask stopper G; a filling-tube H, with india-rubber tubes and pinch-cocks; and tubes N, fitted in an india-rubber cork for regulating the water-line—the longer tube O reaching to the zero mark when placed in the neck of the bottle. There are also two vessels J, to draw off the reagent, &c.; and a burette, divided into cubic centimetres, for titration, and for letting the reagent into the flask stopper.

Manipulation of the Apparatus.

To fill the bottle with gas, place the tubes H in the neck, and connect to the gas-main with the tube which reaches to the bottom of the bottle. Then allow the gas to pass in until all the air is driven out, after which place the pinch-cocks on the two tubes 1 and 2. If it is required to draw a sample of gas from flues, an aspirator should be connected to the short tube. Having filled the bottle, place it on the stand attached to the trough K, with the neck under water, and proceed to regulate the water-line in the following manner:—Remove the tubes H from the neck of the bottle, and replace them by the tubes N. The tube O should have a piece of india-rubber tubing fitted on, long enough to rise above the water in the trough K. Adjust the bottle so that the water on the outside is level with the zero mark; then remove the pinch-cock previously placed on the india-rubber tube, and the water will rise within the neck to the top of the tube O (which should be level with the zero mark), and the gas will pass out through the india-rubber tube O—thus equalizing the pressure and adjusting the water-line. The bottle should be allowed to stand in the room where the testing is to be carried out a short time before the above adjustment is made, for the purpose of equalizing the temperature. This being accomplished, remove the tubes N, and place the flask stopper G in the neck with the pinch-cock L removed, so that the water can pass freely into it, after which replace the pinch-cock, and proceed to absorb the gases to be tested for, thus: Suck off into the flask J nearly all the water contained in the neck and stopper; then allow a measured quantity of standard absorbent to be drawn up into the flask out of the burette M, taking care that no air passes

in. This absorbent should be slightly in excess of the gas tested for; and a little distilled water should be passed in afterwards, so as to carry it all into the bottle. Shake up thoroughly; and when absorption is complete, draw off the solution into a clean flask J. Place the neck in water; remove the stopper, and allow the water to rise in the neck; lower the bottle until the water-lines are equal, and read off the absorption. Afterwards put the solution used aside in a clean bottle, to be finally titrated with a standard solution and an indicator as described below.

Methods of Using the Apparatus for Testing.

Ammonia.—Pass an excess of solution of sulphuric acid into the bottle, 1 c.c. of which will absorb 1 c.c. of ammonia; titrate with solution of potash, one cubic centimetre of which is equivalent to 1 c.c. of sulphuric acid solution. Say that 5 c.c. of sulphuric acid were used in the bottle, and 2 c.c. of ammonia solution were required to neutralize this in titrating, then the sulphuric acid has absorbed 3 c.c. of ammonia from the litre of gas treated. Then, as there are 1000 c.c. in a litre, this equals 0.3 per cent. Compare this with the reduction in volume previously noted, and if they correspond the test is accurate.

Sulphuretted Hydrogen.—A standard solution of acetate of lead is used, 1 c.c. of which will absorb 1 c.c. of sulphuretted hydrogen. This is let in in the same way as the sulphuric acid, but not in excess. A piece of acetate of lead paper should be passed up into the bottle, and the lead solution added until all the sulphuretted hydrogen is absorbed, which is shown by the lead paper remaining white; the amount of solution used being noted. If 10 c.c. has been used, this equals 1 per cent. of sulphuretted hydrogen, and can be converted into grains per 100 as described below. This latter test will spoil the sample of gas, as it is next to impossible to prevent air being admitted when the lead paper is passed up into the bottle. Therefore a new sample should be taken for further examination. Of course, if it is not wished to test in the way described, it can be done by absorption, only using acetate of lead solution (which need not be standard), and reading off absorption after equalizing the water-lines.

Carbon Dioxide.—A standard solution of barium hydrate is used for this test, 1 c.c. of which will absorb 1 c.c. of carbonic acid. This is titrated with a standard solution of hydrochloric acid, 1 c.c. of which is equal to 1 c.c. of barium hydrate solution. Phenol phthalein is used as the indicator.

The three foregoing constituents being the principal ones, the following are only tested for by absorption. The first three may also be found in this way, in which case standard solutions are not required; but I think the methods described are the best.

Hydrocarbons.—Naphtha is used as the absorbent; the water-line being equalized, after washing out, with a solution of potash.

Benzene.—This may be tested for by absorbing with fuming nitric acid, and washing out with potash solution.

Oxygen.—Concentrated solution of pyrogallie acid and potash are used; and the bottle washed with distilled water.

Carbon Monoxide.—By means of cuprous chloride, &c.

Corrections for temperature and pressure may be made as follows:—Suppose, for example, that we find 3 c.c. of ammonia at 64° Fahr. and 29.6 inches bar., then as the tabular number given in (the late) Mr. Hartley's table of corrections is to 1000 (the contents of the bottle in cubic centimetres at 60° Fahr. and 30 inches bar.), so is 3 c.c. to the corrected amount—viz., as 976:1000::3=3.072; or as 10 c.c.=1 per cent., then 3.072 c.c. equals 0.3072 per cent. of ammonia. Then, to convert to grains per 100 cubic feet of gas: As 1 per cent. is to 0.3072, so is the weight of a cubic foot of ammonia to the grains per 100 cubic feet—viz., as 1:0.3072::316.77=97.311 grains of ammonia in 100 cubic feet of gas. This amount is not taken from an actual test, but only assumed by way of example.

Weight of Gases in Grains and Grammes.

Name.	Weight of 1 cub. ft. in grains, at 60° and 30 in. bar.	Weight of 1 c.c. in grammes, at 60° and 30 in. bar.
Hydrogen	37.09	0.0008389
Ammonia	316.77	0.0071390
Carbonic oxide	519.18	0.0117153
Oxygen	593.59	0.0133895
Sulphuretted hydrogen	630.69	0.0142587
Sulphuric acid	820.92	0.0184110
Bisulphide of carbon	1417.41	0.0318445

It may be mentioned that the bottle above described answers admirably for analysis of chimney or furnace gases. In a further communication, I will give a description of a modification of Harcourt's colour test, which I have used with great success, and which I think is more simple and accurate than any gas burette or bottle can be for testing for ammonia, sulphuretted hydrogen, carbonic acid, and bisulphide of carbon in coal gas.

The bottle, &c., referred to can be obtained from Messrs. Townson and Mercer, of London, and costs about £2 5s. The standard solutions and absorbents may also be had through the same firm.

THE BOSTON WATER-METER TESTS.

By INSPECTOR.

The use of water-meters has long been a recognized system with most American Water Companies; and valuable information has been added to water-works literature from time to time by the

many mechanical experts engaged in the distribution of water. Very large numbers of meters are employed in America, not only for trade purposes, but for domestic supplies; and although numerous tests had been made by nearly all the Companies, yet the Boston Water Board deemed it necessary to appoint a Commission of experts to thoroughly test and report on the principal meters in the market—not with a view of remodelling the whole service into a supply by meter, as some manufacturers affirm, but rather to decide which meter would prove to be most accurate, durable, and economical, and to supplement the information the department had already obtained by impartial and reliable means under their own immediate supervision and control. The report of the Commission has now been received. There were 35 machines entered for competition or test; and 26 were tested as nearly as possible under the conditions prevailing in actual working, with the same length and size of service-pipe as generally used under ordinary pressures. When, however, examinations were being made under different heads, the meters were attached to pipes connected to large tanks fixed at different altitudes throughout the building. A steam-pump was provided to work a pressure of 200 lbs. per square inch; and all meters manufactured to stand it were put under that pressure.

The meters were first tested for accuracy of registration and measurement, before being subjected to any work; and afterwards put on a durability test—that is, the meter is allowed to work for a term in which it will pass as much water as, in ordinary circumstances, would flow through it in a year. They were next submitted to an intermittent test—that is, the meter stands idle for various lengths of time, and is restarted under circumstances arranged similarly to ordinary usage. Finally, after these tests were made, and each meter had done its fair share of work, it was tried for accuracy, and was then taken to pieces, every detail carefully examined, and its defects noted. All the arrangements for carrying out the tests were most elaborate. The measurement of water by weighing was adopted; and to ensure perfect correctness, an electrical device was employed to stop the flow of water as the scale tipped with the required weight. Gauges were fixed on the inlet and outlet of each meter; and careful tests were made with back pressures varying up to 50 feet, which were carried out by the use of tanks fixed on different floors of the building. A full description of the arrangements employed for the conduct of these tests was given in the JOURNAL for July 5, 1887 (p. 27).

First Accuracy Test.

	Error of Meter.				No. of Experiments.	Retardation.		
	Minimum per cent.	Maximum per cent.	Average per cent.	Range of per cent.		Friction per cent.	Flow decreased per cent.	Time increased per cent.
<i>Note.</i> —The minus before figures of percentage indicates registration of less water than was actually passed. The absence of a sign indicates the contrary.

Several of the meters failed to stand the durability test; being altogether too weak, and of light construction. Therefore in the second test for accuracy, only fifteen meters are included. There

are failures enumerated; and some meters are mentioned as having merit, but cannot be approved owing to complicated mechanical arrangements.

The meters that have the approval of the Water Board are commented upon as follows: "The remaining meters tested by the Commission seem to classify themselves into three groups—The 'Crown,' 'Hersey,' and 'Shedd' rotary meters; the 'Union Duplex,' 'B.W.W.,' and 'Worthington' improved horizontal acting, double-piston meters, the 'Frost,' 'Hood' No. 1, and 'Star' vertical acting, slow-moving, single-piston meters; and while, perhaps, no one of them can be unreservedly recommended or considered as a perfect meter, it is believed that, with certain modifications that have suggested themselves during the tests here reported, all of them may be looked upon as reliable within specified limitations for general use."

In regard to each of the first six meters thus classified together, the same remarks apply. The range of error was considerable, with a general tendency to over-register more, or under-register less with a small than with a large discharge of water, but the effect of wear upon the error was very slight. All had rubber bunters to receive the blows at the ends of the piston strokes; and these, by their battered condition, showed that they had seen hard service. If they are not renewed before being completely worn out, it would appear as though the meter might be seriously damaged by the action of the pistons. As the force of these blows would greatly depend upon the head of water, it would seem advisable to limit the use of meters of this class to places where the pressure was not very great—say, not exceeding 50 or 60 lbs.

The range of error does not differ much; but the effects of continued wear are more apparent in the "Star" than in the "Frost," and more in the "Hood" than in either of the others. The friction developed in all these meters is considerable; but the motion is so free from violence that they could be safely used with pressures that would be fatal to more rapidly-moving pistons.

DEATH OF DR. CLAUSIUS.—Dr. Clausius, Professor of Natural Philosophy at the University of Bonn, died on the 24th ult., aged 67. The name of the deceased gentleman will long be memorable as the demonstrator, if not the originator, of the mechanical theory of heat.

SOUTH WEST OF ENGLAND DISTRICT ASSOCIATION OF GAS MANAGERS.—The programme for the usual autumn meeting of the Association has just been issued by the Honorary Secretary, Mr. Norton H. Humphrys, of Salisbury. The members are invited to assemble at Weston-super-Mare on Tuesday next, the 11th inst., when the proceedings will include a visit to the Weston-super-Mare Gas-Works, a meeting at the Queen's Hotel, and afterwards the usual social dinner. So far as may be judged from the number of applications for membership to be considered at this meeting, the Association is in a flourishing condition. The President will open the meeting, after the usual routine business (such as election of officers for ensuing year, &c.), with a few remarks. A paper on "The Hydraulic Main, and Retort-Bench Bracings" will be read by Mr. John J. Jervis, of New Swindon; Mr. William Davis, of Poole, will discourse on "A Remedy for Naphthalene"; and Mr. A. Thomas, of Cowes, will describe his "Improved Pressure-Gauge." These three papers, with the usual discussions, will no doubt fully occupy the time that is allotted for the meeting.

PRESENTATION TO MR. L. T. WRIGHT BY THE NOTTINGHAM GAS COMMITTEE.—On his retirement from the position of Engineer and Manager of the Nottingham Corporation Gas Department, the Gas Committee presented to Mr. Lewis T. Wright a handsomely illuminated address, containing an extract from the minutes of their meeting on the occasion when Mr. Wright's resignation of office was accepted. The address, which was surrounded by a beautifully executed design and surmounted by the borough arms, was signed by the Chairman and Vice Chairman of the Committee, Messrs. Barber and Ford, and the Town Clerk, Mr. S. G. Johnson. It was worded as follows:—"At a meeting of the Gas Committee of the Town Council of Nottingham, held on the 14th day of June, 1888, Mr. Lewis Thompson Wright signified to the Committee his desire to resign the office of General Manager and Engineer of the Gas Undertaking of the Corporation, in consequence of his having received the appointment of Engineer and Manager to the Buenos Ayres (New) Gas Company in the Argentine Republic. On the motion of the Vice Chairman of the Committee, Mr. Alderman John Parr Ford, seconded by Mr. Councillor Richard Fitzhugh, J.P., it was resolved that the Committee accept with great regret the resignation of Mr. Lewis Thompson Wright, and desire to convey to him the thanks of the Committee for the successful way in which he has conducted the works of the Gas Undertaking during the five years he has held his present appointment. The Committee desire to place upon record their high sense of the great value of Mr. Wright's services as Manager of their Gas Undertaking, both in the manufacture of gas and of residual products, and generally as a man of business affairs. The Committee also desire to state that they have found Mr. Wright to be a pleasant official to work with, well versed in all matters pertaining to the construction and maintenance of gas-works, the manufacture and distribution of gas, the manufacture of sulphate of ammonia, and the distillation of coal tar; and that he has shown himself to be a gentleman of the highest integrity, of excellent judgment, and thoroughly upright in all his conduct."

Technical Record.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.

THE QUARTERLY MEETING AT DONCASTER.

As briefly reported in the JOURNAL last Tuesday, the Seventy-fifth Quarterly Meeting of the Manchester District Institution of Gas Engineers was held at Doncaster on the 25th ult.; and beautiful weather, a meeting at which there was expounded a theory as novel as it is daring and important, and a delightful drive through pleasant scenery to a romantic and interesting ruin, were the characteristics of the gathering. Doncaster is on the very verge of the eastern border of the Institution's operations; but nevertheless it was altogether a highly successful meeting, and the proceedings combined a due admixture of business and pleasure. The Lancashire members assembled in rather moderate numbers; the holidays and the distance from home being rather against a strong muster. Compartments were reserved for them in a through carriage attached to the 10 a.m. express from London Road Station, Manchester; and the journey was made pleasantly and in good time. There were several additions to the party before Doncaster was reached; and the final result was a fairly average attendance. At the station, the members were met by Mr. Robert Bridge, the Engineer and Manager of the Doncaster Corporation Gas-Works, and were conducted to the Elephant Hotel, where luncheon was prepared. Immediately this was over, an adjournment was made to the Council Chamber of the Town Hall, which was placed at the service of the Institution by the Mayor (Alderman Wainwright) for the ordinary business meeting. The President, Mr. T. Duxbury (Darwen) was in the chair; and the business occupied something less than a couple of hours. It began with the reading by the Honorary Secretary (Mr. Harrison Veevers, of Dukinfield) of the minutes of the last meeting—the pleasant gathering held in May in Northwich, the centre of the Cheshire salt district. The record was pronounced correct; and then two new members were added to the roll—viz., Mr. Tom Settle, Manager of the Gas-Works, New Mill, near Huddersfield, who was nominated by Mr. J. Booth (Southport), and seconded by Mr. W. W. Hutchinson (Barnsley); and Mr. William Drewry, Manager of the Gas-Works, Cleethorpes, who was proposed by Mr. Thomas Newbigging (Manchester), and seconded by Mr. Harrison Veevers. Some slight discussion followed, as to the wisdom of making a departure from the printed programme. According to this, Mr. Newbigging was down to read a paper on "Gasholders without Upper Guide-Framing," which in its turn was to be followed by the long postponed discussion on Mr. J. Dalgliesh's paper on "Oil and other Illuminants, and their Effect on the Consumption of Gas." The President invited an expression of opinion as to the wisdom of reversing the order of the two; and explained that Mr. Dalgliesh was unfortunately unable to attend the meeting, but had sent an addition to his paper, which he wished to have read to the meeting. Mr. Veevers explained that the reason for putting Mr. Newbigging's paper first was that it was a definite subject, which would occupy a definite amount of time; while the discussion on the deferred paper might or might not last for hours. No disrespect was, of course, intended to Mr. Dalgliesh; the sole idea being to simplify the proceedings of the afternoon. The vote was largely in favour of keeping to the order of things as arranged; though Mr. Newbigging remarked that, had Mr. Dalgliesh himself been present, he should certainly have insisted upon the discussion of his paper being taken before any other paper was read. However, as that gentleman was absent, and as it might be the desire of some of them to see his supplemental paper in print before they discussed it, he would not press the matter. Without further preface, Mr. Newbigging proceeded to read his paper, which appeared last week, pp. 373-4; explaining the invention by which Mr. W. Gadd, of Manchester, proposes to dispense with the upper guide-framing of gasholders, while imparting to them, as he contends, greater rigidity. The action of the patent was experimentally illustrated by means of a couple of models—one of a single-lift, and the other of a three-lift holder. An informal conversation followed, in which a number of questions were asked and answered. A report is given below. The formal discussion, however, was adjourned till a future meeting; but thanks were voted to Mr. Newbigging for his paper, on the motion of Mr. W. Carr, seconded by Mr. W. W. Hutchinson. It was now within about a quarter of an hour of the time for adjournment; and the discussion of Mr. Dalgliesh's paper was again postponed. His supplementary observations were appended to our report last week (p. 374). Thanks were voted to the Mayor, at the instance of the President, seconded by Mr. C. E. Jones (Chesterfield), for allowing the use of the Council Chamber for the meeting; and the resolution was acknowledged, on his Worship's behalf, by Mr. Alderman Spencer. And so the meeting came to an end.

Conisbro' Castle, an interesting ruin associated with the early history of the country and with romance in the pages of Sir Walter Scott's "Ivanhoe," was the next object of attention. It is situated about five miles from Doncaster; and wagonettes were provided to convey the party to it. The drive was through pleasant scenery, past fields of waving corn, and gardens gay with flowers. The Keep of the Castle is in an excellent state of preservation; and most of the visitors climbed the narrow stairway (carried through the thickness of the wall from storey to storey) until they reached the top, and enjoyed the view. The castle itself is interesting, alike from its antiquity and the singular character of its design; while the view, which embraces a consider-

able stretch of the valley of the Don and the country round about, well repaid the climb. The drive back to Doncaster was accomplished just in time for tea; and then followed a little convivial gathering, at which several toasts were drunk. One of these was that of "Kindred Institutions," in connection with which the new North of Ireland Association of Gas Managers was especially mentioned, with good wishes for its future success.

GASHOLDERS WITHOUT UPPER GUIDE-FRAMING.

After Mr. Newbigging had read the paper given last week, Mr. Gadd (as intimated above) proceeded to illustrate by means of models—one of a single-lift, and the other of a three-lift holder—the action of the invention. In the single-lift holder the guides were placed at an angle of only 60°.

Mr. NEWBIGGING remarked that the invention was so simple that anybody could understand it. There had been a good deal of difficulty in preparing a model of a three-lift telescopic holder, because the cups between each lift could not be made the necessary depth to stand the pressure; so they had had to overcome the difficulty as best they could.

As a test, weights equal to four times the weight of the bell were placed on the one side of the single-lift holder.

Mr. W. CARR (Halifax) pointed out that, under this test, the holder went down with a jerky motion, instead of steadily.

Mr. GADD explained that the model was roughly made, and that this partly accounted for the want of steadiness; while a little water which had found its way into the pipe was also against the success of the experiment. The weights were afterwards distributed, so as to more adequately represent the pressure which would be exerted by snow; and the jerking was then less perceptible.

Mr. W. W. HUTCHINSON (Barnsley) suggested that when the gas-holder was very nearly full, it would be unstable, and might easily be blown over.

Mr. GADD contended that the holder was always in a condition of stability, unless, as was improbable, the wind lifted it bodily out of the tank.

Mr. D. CLARKE (Ashton-under-Lyne) thought that the plates and rollers would have to be stronger than in a holder of the ordinary kind.

Mr. GADD admitted that the details of the structure certainly might require a little modification.

Mr. NEWBIGGING said he thought the vertical support ought to be stronger, and that it should take the shape of a girder of triangular form. In connection with the model of the telescopic holder, he explained that two of the series of guide-rails had been placed one way, and (unintentionally) the third the opposite way; the result being that, after turning in one direction, while the two upper lifts were being raised, the holder turned in the contrary direction during the filling of the third lift. Referring to the pressure exerted with a view to overturn the model, he said that in so small a model a very little push with the hand represented an abnormal wind pressure; but, to his mind, a holder on this principle would be perfectly rigid under even an extraordinary pressure, owing to the locking action of the rails and rollers.

Mr. ISAAC CARR (Widnes) asked if the suggested triangular girder would be from the top to the bottom of each lift.

Mr. NEWBIGGING said it would not, only in the inner lift. His idea was that, if more strength was needed, it should take the form of a girder.

Mr. I. CARR maintained that it would not strengthen the structure, because the whole strain would come against the bottom sheet.

Mr. NEWBIGGING pointed out that in the outer lift of a telescopic holder, the additional strength, if any were required, would be furnished by the guide-rails.

Mr. GADD added that the question of strengthening the holder internally was a matter for experiment, and one in which they would be guided by experience.

Mr. NEWBIGGING said the inherent weakness of the ordinary gasholder consisted in the want of a positive bottom bearing; and they had this in the present invention.

Mr. GADD pointed out that the pressure was centred on one point at the top; the roller at the bottom was one leg of the lever at which the pressure was being exerted. The roller on the opposite side was resisting that pressure; and this leg of the lever was twice as long as the other. The power was diminished by having a short lever actuating; and the force was always exerted downwards to the rollers. The only thing he could possibly conceive as tending to danger was that, if there was a hurricane sufficiently strong, the plates might be stripped away; but in this respect there would be no difference between his arrangement and an ordinary holder.

Mr. I. CARR considered that very great care would require to be taken in getting the guides an equal distance apart.

Mr. GADD said he was glad that matter had been noticed. It was a point which had occupied a great deal of his attention in working the question out. Although it was highly desirable that something like accuracy should be exercised, still he had, apart from that, made provision for any slight inequalities. This provision was in moveable centres to the rollers or slides; and this would allow for slight inequalities. He had made experiments with a number of rollers arranged in a plane; and where they had been fixed at slightly diverging angles even, he had been able to keep the apparatus square and run it up and down.

Mr. HUTCHINSON asked what would be the effect of a small stone or piece of wood getting into the grooves? It might be possible,

he feared, for two or three small stones to do a great deal of mischief.

Mr. GADD said it would be difficult, if not impossible, to lodge stones in a groove the angle of which was 45° ; and wood would simply rise to the surface of the water.

The PRESIDENT said the principle of constructing a gasholder explained by Mr. Newbigging was so novel and so contrary to the received notions of what is and ought to be done, that they could not attempt to discuss the paper adequately that day. They had better, therefore, defer the discussion until the next meeting; before which the members could read the paper and consider the matter carefully. But as they had Mr. Gadd present, he should have pleasure in hearing anything he might wish to say; and advantage might also be taken of the opportunity to put to him any questions which they might wish to ask.

Mr. W. CARR said he should like to make a remark or two, and put some questions; and it would perhaps facilitate Mr. Gadd's reply if he did it in a formal way, because it was confusing to anyone to have questions put from three or four sides of the table at once, and to be expected to answer them all satisfactorily. Like every other member of the Institution, he came there quite at sea as to what kind of principle they were going to have explained; and he was both surprised and pleased at the plan submitted to them by Mr. Newbigging. At the same time there were one or two points—he did not know whether or not they would be looked upon as objections—that he wished to draw attention to. Of course, it was very easy for them to sit there and say: "It is a very good thing, and we like it;" but the point was this—Would they adopt this plan when they came to put up a new gasholder? Personally, he should not like to say that he thoroughly agreed with anything he saw there, unless he felt so much in accord with it as to recommend its adoption at his own works. One of the most important objections which occurred to him was this—that when the first lift was filled, and the second half filled, the rollers would be midway up the third lift; so that if any wind pressure then came, the whole of the strain would be upon the guides supporting the sheets of the third lift. The locking power was perfectly easy to understand when the idea of the screw motion was grasped, because any vertical or horizontal pressure would be resisted by the whole screw when once it was fairly in the thread. So it would be in this case. But the strain must be taken somewhere; and it would have to be taken by the guides and the sheets midway between the coping and the bottom of the third lift, which he took to be the weakest point. He thought the chances were that distortion would be caused if the pressure were very great at any particular point of the holder, because there was nothing to take it but the guides or the sheeting. If this happened, distortion might take place, with the effect, he was afraid, of upsetting the gasholder. To his mind, this was the weakest part of the construction. In the single-lift holder this objection would not obtain at all, as the guides had a perfectly rigid backing from top to bottom; and the pressure might come at any point from top to bottom, and had a perfectly rigid system to transfer itself to. But it was not so when one lift was working inside another, especially at the point when one lift was getting half way up, and having nothing but the sheeting to resist it. He mentioned this because Mr. Newbigging had said in his paper that no additional weight would be required. Consequently, if there was no extra weight, they would have only the ordinary thickness of sheeting, and nothing else, to resist the strain. Another point he should inquire into would be that of the rollers. The rollers would have to be in working order; and Mr. Gadd had only complicated matters by saying he would have some with a horizontal sliding motion. In an ordinary way, a certain amount of deposit took place on the rollers; and the time came when the rollers did not revolve. In vertical slides this did not matter very much, if the slide was true, and the roller a good fit. It simply went up and down, and formed a rigid face; and he believed that in nine out of every ten slides the rollers simply formed a bearing, which slid up and down the guide-rails in the tank. This was a consideration which would have to be carefully taken into account by anyone adopting this plan. There was a third point. Mr. Newbigging said that the ordinary method of counterbalancing small holders would be dispensed with by increasing the length of the roller-path, which could be done by placing the guide-rails in the tank at a less angle. He (Mr. Carr) did not understand how that would dispense with the counterbalance. He believed even with a single-lift holder much greater strength would be required in the lower curb, because if the strain was to be received by the lower curb, a much stronger curb would be required than now. As a rule, the bottom curb was made too weak; and it would be necessary that it should be strong in this case. These were a few points which occurred to his mind; and they were questions which would have to be answered before anyone could put any of these holders to work. If they could be satisfactorily answered, he did not see why they should not adopt the plan, and dispense with guide-framing. There seemed to be a great deal in it; and if they could save 50 per cent. of the cost, he did not think they would be justified in going on as now.

Mr. C. E. JONES (Chesterfield) asked of what material it was proposed to make the rollers and the internal guide-framing? This was not stated in the paper; and it would be well to know it. He should also like to ask whether any time had been really taken up in testing the machine, which was of a very novel, daring character, and conferred upon the author a considerable amount of praise for his ingenuity and boldness in departing from the old lines. Had

any experiments been made with different waters, and their action upon the rollers and the guide-framing? It appeared to him that if they used cast iron, they would have to fill the tanks with distilled water, because with some water the grooves and guides would certainly in time become filled with corrosion, which would largely increase the friction, and throw more strain upon the sheeting. The weak place in the holder when above ground would be towards the bottom plate—the point of greatest leverage; and this would have to be very materially strengthened, which would add largely to the weight of the structure. It was a most extraordinary invention, and very beautiful in its action, as worked before them. The idea of making a gasholder into a screw, and guiding it from the bottom roller, entitled the author to their highest admiration; and the excellent manner in which Mr. Newbigging had put it before them deserved their thanks.

Mr. GADD, in reply, said he had not made any experiments with materials or water; for the simple reason that the rollers and other parts of the structure were placed in similar positions to those they occupied in ordinary gasholders. If water would destroy the new rollers, it would destroy the old ones. He could not see where any new principle came in as to this. The rollers and guides upon his system would not last for ever, any more than they would on the old plan. No doubt a certain amount of corrosion would take place; but he failed to see that there was any difference in the conditions, with regard to the water attacking the details of the structure, between this and the details of construction of ordinary gasholders. Mr. Carr had very properly brought forward several questions which, he said, required to be answered. They ought to be answered; and he (Mr. Gadd) would try to answer them. He would first of all take the last objection which Mr. Carr made—namely, that the rollers would set fast, and cease to revolve. Perhaps this would be so; but the fact was that he only put in the rollers in deference to received opinion. For his own part, he should prefer to make the guides without rollers at all. The single-lift model had been worked without any rollers at all—simply with solid sliding-pieces (solid pieces of metal cut at an angle). It required nothing more; and if he were a practical gasholder constructor, erecting a holder on his plan, he would advise that anything like revolving rollers should be dispensed with, because he could understand that rollers immersed in water which contained material tending to disintegration, would set fast. Rollers were put on the model, and in the diagram, simply in deference to present ideas as to the mode of construction. Another important consideration to which Mr. Carr had referred was that of the position of the second lift. There was no doubt that when the holder was in the position described by Mr. Carr, it would be in its most vulnerable condition; but he should certainly think that, with proper construction, it would be sufficiently strong for any possible purpose, and would resist any pressure that could be brought against it. In the first place, he should never expect or dream of putting pressure upon the sheeting; he should not think of doing so in an ordinary gasholder. The pressure must be taken up by the framing of the holder. He took an ordinary holder to be something like an umbrella. There were the ribs; and there was also the canvas which covered it. The sheeting was only like the canvas of the umbrella; and it was in the mechanical construction of the frame which carried the sheeting that strength was obtained for resisting the strain. Consequently there should be a frame—a rigid frame—underneath the sheeting of each of the lifts. This frame was provided by the angular guides; though these, of course, could be strengthened, because it was not necessary to have rollers to each of them. Each was attached to a fairly rigid ring top and bottom; and there should be a fairly rigid frame. The sheeting was only to keep in the gas. This was his idea, from the engineering point of view; and to his mind it was very simple. If the present mode of putting sheets on was not suitable to this plan, it must be abandoned; because there was no reason why every present idea should be slavishly followed, and Mr. Carr, with his ingenuity, would not be slow to adopt some new method to suit the new ideas. He was glad that Mr. Carr put his finger upon this objection; because it was very desirable that the thing should be tested at this and every point. What he (Mr. Gadd) wished to point out was that this was a weakness of a constructive character, which any constructive engineer would find means to overcome. It was not necessary to increase the weight; because, as they knew, weight could be added without increasing strength. It was a question of form, and of so constructing the holder as to meet the strain which would come upon it. Gas engineers were quite able to meet all these cases. The question to ask with regard to this proposal was, Was it progress? If it was progress—if it simplified the matter, and made it cheaper, then it was natural they should desire to follow it. As to the æsthetic question which Mr. Newbigging had referred to, this occurred to him at the beginning, but afterwards the simplicity of the structure without framing commended itself to him. After all, a simple structure was a grand thing; and a three-lift gasholder on his plan would have something of the simplicity of the pyramids of Egypt. (Laughter.) He was not at all sure that there was not something æsthetic about it after all. At all events, if there was the element of cheapness, the æstheticism might have to go to the wall. With reference to the counterbalance, what Mr. Newbigging meant was this: That, if they had a flat angle of an inclined plane, there was more of the weight of the holder on the rails, and less on the gas. [Mr. Carr dissented.] Mr. Carr shook his head; but the proposition was capable of demonstration. The steeper the angle, the less of the weight of the holder

would be taken off the gas; the flatter the angle, the more of the weight of the holder would be sustained by the rails and taken off the gas. In taking a wheelbarrow up a plank, the steeper the incline the greater would be the power required to be exercised at any given time. The flatter the angle and the larger the path, the less force would have to be exerted.

Mr. NEWBIGGING remarked that, in resisting a strain, this method of guiding a holder had many advantages over the old system; because, as he had already mentioned, whenever any force was exerted, the whole of the guide-framing came into action, back and front and sides—one-half of the rollers being in tension and the other half in compression.

Mr. GADD said that Mr. Carr thought the rigidity of the bottom curb would want to be much increased. If they would consider the thing in reverse—that was to say, if the flanges of the rollers or solid sliding-pieces were put outside instead of inside, they would place the ring, instead of in compression on the strain, in tension. So they could practically work with a very flexible ring indeed. What he meant was that if the flange were put on the outside of the rollers of the outside lift, instead of inside, any pressure at the top would cause the stud to pull at the roller and the roller flange, so that the strain would be put upon the rollers in tension, tending to pull them away from the tank instead of pressing them in. As it was now, there was a compression both of the roller towards the tank and of the ring itself. If necessary, both methods could be adopted; and they could have two grooved rollers with a flange between. He did not, therefore, think it really necessary that the bottom curb should be strengthened to any material extent; but if it were, it seemed a comparatively small matter as against the great gain of taking away the guide-framing.

The PRESIDENT said nothing but benefit could follow from the conversational manner in which they had discussed the matter; but the formal discussion would be postponed till the next meeting.

Mr. W. CARR then rose and said he had considerable pleasure in moving that their thanks be given to Mr. Newbigging for his paper. He had done them very great honour indeed in submitting it first to the Institution. It showed the warm interest which he took in the Institution, and the good feeling he had towards it, that he should honour them by bringing the idea before them, before submitting it through another source. He should have been very sorry if he had not been present at the meeting; though he had no idea that they were going to listen to a paper descriptive of such a weighty departure in gas-works engineering. He did not see why they should not have gone on discussing it as hard as they could, and then discuss it again at another time. For his own part he had not attempted to discuss it; the remarks he made he put more in the form of questions. As to the æsthetic question, he thought that this might be left out of consideration. People already talked of a thing being "as ugly as a gasometer;" and their views were not likely to be altered. As to the question of counterbalancing, both Mr. Gadd and Mr. Newbigging were at fault; and he thought it would appear plain to them when they came to think of it. He had very much pleasure in moving the resolution he had mentioned, and to add to it his own warm feeling of regard for Mr. Newbigging.

Mr. W. W. HUTCHINSON seconded the motion. He agreed with Mr. Carr that great honour was done them by Mr. Newbigging putting this matter before them at a time when it was one of the great questions of the day. While he thought the gas profession had somewhat redeemed the name it had for the ugliness of its gasholders, and had of late years made them more presentable, they were likely to revert to the simple grandeur of the pyramids. In considering this invention, they would, however, have to think of their neighbours. They could not disregard what might, to uninformed minds, appear to be the dangerous nature of the structure.

The PRESIDENT said he had very great pleasure in putting the motion. Mr. Newbigging, he considered, was entitled to their best thanks.

The resolution was unanimously carried.

Mr. NEWBIGGING, in responding, thanked the members for their hearty and unanimous vote, and said he had been much struck with this invention, and very willingly undertook the duty of writing a paper upon it. He wrote it without communicating with Mr. Gadd; but when he came to consider the matter of the counterbalancing, he could not make up his mind upon the question whether they could dispense with the counterbalance weights by placing the guides at various angles. Accordingly, he called on Mr. Gadd, and discussed the question with him at length—he (Mr. Newbigging) taking the view held by Mr. Carr, and Mr. Gadd successfully combating his arguments.

SPIRAL FRAMED GASHOLDERS.—We have received a letter from Mr. W. F. Mason, of Manchester (who is associated with Mr. Gadd in the invention brought so prominently before the gas profession through the paper read by Mr. Newbigging before the Manchester District Institution of Gas Engineers last Saturday week), in which he says: "It may be of interest for the readers of your JOURNAL to know that a member of one of the largest firms in the country has been to see the model of the 'Manchester Patent Gasholder,' and on behalf of his firm offered to purchase the British patent for £20,000. This I declined; as I place a much higher value on the invention. I may say that we are protected in every country in the world where gas is used."

THE "METEOR" GAS-LAMP.

WESTPHAL'S PATENT.

We have recently had an opportunity of seeing some specimens of a new high-power gas-lamp (the invention of Herr C. Westphal, of Berlin), exhibited at the offices of Messrs. Henry Greene and Sons, 155, Cannon Street, E.C., who have been appointed Sole Consignees for Great Britain, Ireland, and the Colonies. This is the lamp, we are informed, which was alluded to at a meeting of the Commissioners of Sewers of the City of London (when the question of lighting a part of the City with the electric light came up for discussion) as being likely to rival the electric arc light in intensity. This naturally was reported in the public press, with the result that representatives of two of the London Gas Companies have seen the lamps, and are now engaged in testing them, with a view to introducing them as a rival to the electric light.

The lamp itself is of very simple construction—entirely free from intricate workmanship. The principal parts are of cast-iron; and the lamp cannot, therefore, get out of order. No sheet iron, nor any kind of stamped or spun metal, is used in its manufacture, except for ornamentation; and this may either be of brass, copper, iron, or other metal, or, if highly ornate decoration is desired, it can be of Doulton-ware, faience, or other art pottery.

The burner is, however, the special feature of the lamp. It consists of two concentric rings; the space between forming the passage for the gas from the gas chamber to the point of ignition. This circular space is perfectly open; and it thus allows the gas to pass forward without check or interruption. The flame burns at a distance of about $\frac{1}{2}$ inch from the orifice of the burner, which tends to keep it cool, and prevent the deposit of carbon, so often complained of when drilled burners are used. If any dirt should by chance accumulate, it can be easily removed by passing the blade of a pen knife, or a piece of watch-spring round the inside of the orifice—an operation only occupying a few seconds, and one that cannot possibly injure the burner. This cannot, we believe, be accomplished with any other high-power gas-burner. The flame is quite different from that of any of the high-power burners hitherto introduced, inasmuch as it burns from the circumference to the centre, instead of from the centre to the circumference. Consequently there is no dark disc in the middle; but the whole of the flame is (to quote the patentee's words) "one mass of intense white meteoric brilliancy." Another point greatly in favour of this lamp, is the small size of the body compared with that of the flame, so that the walls, and even part of the ceiling of the apartment in which the lamp is fixed, are well illuminated and free from shadow. It is thus admirably adapted for lighting picture galleries, libraries, museums, &c.

Like all other high-power gas-burners, the "Meteor" lamp readily lends itself to, and is easily adapted and fixed in connection with any of the ordinary appliances of ventilation. The principal point to be remembered is the necessity for carrying the horizontal ventilating-pipes into a chimney or flue in which there is a good up-draught. It is not, however, considered advisable to carry them into the open air, as the ascensional force of the products of combustion given off by the lamp when first lighted would not be sufficient to overcome the weight of the outside atmosphere, especially in winter time.

In the competition between gas and electricity for illuminating purposes, gas engineers must make the best use of their speciality—that is, get the utmost possible duty out of the gas employed; and the "Meteor" lamp marks another step in the direction of "proving that gas can hold the field against all competitors"—to quote the words of the report recently presented to the shareholders of the South Metropolitan Gas Company, where the Directors were referring to the exhibitions inaugurated by the Company in various parts of their district, and at which, we understand, specimens of the lamp now under notice were shown.

A GATHERING OF GERMAN GAS ENGINEERS AT LUDWIGSBURG.

In the last volume of the JOURNAL (pp. 513 and 599), we briefly noticed, from the accounts published in the *Journal für Gasbeleuchtung*, the proceedings at the conferences of German gas engineers which took place at Förste and Elbing. We now give an abstract report (translated from the fuller one which appeared in the above-named periodical) of the twenty-fifth assembly of the Mid-Rhenish Association, which was held at Ludwigsburg, in Württemberg, under the presidency of Herr Eituer, of Heidelberg.

After the preliminary formalities had been disposed of, the President opened the business by giving an account of the progress of the Society in the preceding year. In the course of his remarks, he stated that the correspondence had been very voluminous, especially with the Central Association; among the subject-matters being the decision of the Railway Commission to exclude gas undertakings from the benefits of the exceptional rates for coke, the recent vexatious orders concerning the conveyance of spent purifying material, and the experiments made with wet and dry gas-meters. Reference was then made by the President to his visit to Berlin, in response to an invitation from the Committee of the Central Association to attend their meeting. Profiting by his presence in that city, he attended the conference of gentlemen specially interested in the ammonia industry which was then being held there. One important resolution passed was that the Committee of the German Association of Gas and Water Engineers should be instructed to make an appeal to the various gas-works for a subsidy of 1 pfennig per ton of coal carbonized for a term of three years, on the understanding that the proceeds should

be employed in enhancing the value of sulphate of ammonia. The financial position and numerical strength of the Association were then considered by the members; and it was decided to hold the next meeting at Ludwigshafen—a proposition which was most cordially acquiesced in by Herr Lux, the well-known gas engineer of that city.

The first question discussed was that of Sunday labour in gas-works; the subject being introduced by Herr E. Buchholtz, of Offenburg, in special connection with the demands made in this respect by the Factory Inspector of the Grand Duchy of Baden. In the course of his address, he said: The Inspector of Factories (Herr Worrishofer) issued a decree in June last that, in order to "save the health and freshness of the workmen," to quote his own words, in future the operatives engaged in night work should have every third Sunday a complete rest of 36 hours, from six o'clock on Saturday evening till six o'clock on Monday morning. It is within the knowledge of everyone present that the interests of the workmen have not been overlooked by our industry, and that if gentlemen high in authority like the Inspector, instead of being carried away by their questionable zeal on behalf of so-called over-burdened working men would take the trouble to ascertain the real facts of the case, by conferring with the Directors of the large works, such edicts would become an impossibility. They would no doubt find that our night workmen are granted a fully adequate rest, as compared with those engaged in other industries; and that with their sentimental legislation they argue upon wrong premisses, and, instead of benefiting the working men, they really do them harm. Furthermore, they would no doubt find that they actually demand what is practically impossible, and what the workmen, who are well satisfied with their lot, do not think of asking for, not to mention the necessarily higher working expenses caused by the measure. These considerations have not weighed with the Inspector, who has taken his information from the official reports only, and now persists in making his arbitrary measure law. I maintain that our workmen have had that rest which is necessary for them, and consistent with the absolute requirements of our industry. The men who have been under my control for the last 25 years are, without exception, cheerful and happy, and would certainly not derive any benefit from a lengthened enforced rest; and moreover, I am not aware that the Inspector is able to adduce the warrant of existing laws for his obstinacy in enforcing his innovations. I am therefore of opinion that he should be respectfully informed that his order is devoid of legal status, and that, for the reasons adduced, it is impossible to enforce it.

The President, in thanking the speaker for his address, fully endorsed his remarks, and stated it as his conviction that to carry out the order of the Inspector would not be to the benefit of the public, and still less to that of the *employés*.

After some discussion, the following resolution was carried unanimously:—"The Mid-Rhenish Association of Gas Engineers, after having considered and discussed fully the proposals of the Inspector of Factories, dated June, 1886, concerning the Sunday relief of workmen in gas-works, expresses its opinion to the effect—that the putting in force of these proposals would not tend to promote the interests of the employers and still less those of the operatives engaged in this industry."

Herr Lux, of Ludwigshafen, was then called upon to give his promised description of the new works of the South Metropolitan Gas Company at East Greenwich. As this was, in the main, based upon what has from time to time appeared in the *JOURNAL*, it need not be reproduced here. Herr Lux was very cordially thanked for his exhaustive report.

The next matter was the reading of the following paper by Herr Seiler, of Mannheim, on

WILSMANN'S SMOKE-CONSUMING FURNACE.

You are all aware, that the question of the consumption of smoke has gradually pushed itself into notoriety in proportion with industrial progress. At first the police authorities did what they could to assist private individuals who complained by calling upon manufacturers and mill-owners either to abolish, or at least to allay the smoke nuisance from steam-boiler and other chimneys. At last some Governments took up the matter, and sought by legal pressure to provide a remedy; but with only indifferent success. Much has been written upon the question, and to a great measure by people who have no idea of the difficulties which stand in the way of the solution of this problem. Inventors were not wanting who laboured hard to perfect and introduce systems which they contended would be certain to supply the long-sought remedy. But failures in almost all the so-called "smoke-consuming furnaces" produced (furnaces which were either based upon a faulty principle, or were impracticable in their application) have necessarily induced distrust whenever something new in this direction was introduced, and interfered with the more extended application of systems, the efficacy of which had been fairly established in practice. Whilst in the gas industry the generator and shaft furnaces were in general use, the smoke-consuming contrivances for steam-boilers which have been brought into notice have had but an indifferent success, chiefly because the arrangements were, as a rule, found to be very expensive, and out of proportion with existing estimates; though on the other hand, it must be admitted that not only has the consumption of smoke aimed at been attained, but also in many cases a considerable saving in coals realized.

It became therefore a necessity to find out a simple and cheap setting which fulfilled all the conditions of being smoke consuming and economical in the consumption of coals, and which at the

same time was easily and quickly applicable to small works, and equally suitable for coal, wood, or peat furnaces. This long-felt want has been supplied by Herr Wilsmann, Director of Mines at Hagan (Westphalia), by the invention of an exceedingly simple contrivance which he calls a "dike furnace," which can be applied with equal facility in settings for ordinary purposes or for steam-boilers. The arrangement (which is represented in the accompanying illustration as adapted to steam-boilers) consists mainly of a contrivance by which the front part of the fireplace in an ordinary grate-setting is converted into a gas generator. For this purpose there is placed above the grate A, and in immediate proximity to the fire-bridge, a fireproof dike or bank provided with a partition wall C. The effect of this arrangement is that both gas and smoke are prevented from escaping into the flue at the back, if care is taken to pile the fuel against the dam. The gas and smoke generated from the coal which is piled on the grate are consequently forced to pass through the glowing fuel, where they are effectually absorbed.

The gases generated from fresh coal on the top of the burning mass, and which eventually would completely fill the space in front, are directed by the channel B into the flue at the back; and since these gases require a secondary supply of air for their entire combustion, this is provided through the air-tubes DD; the quantity being regulated by dampers.

In employing this system of firing, the chief result obtained consists in the complete combustion of the smoke and gas generated (consequently, a most profitable and thorough employment of the fuel used) and the avoidance of many repairs necessary under the old systems, since in charging the furnaces a cooling of the boilers is entirely avoided. The coals used as fuel are burnt at the beginning of the heating of the boiler, for a space of three-quarters of an hour, in exactly the same manner as in an ordinary furnace arranged after the old pattern, with this difference, however, that the glowing mass of coal is gradually being piled up against the partition until the front section of the furnace is practically closed against the space at the back. During the combustion of the coal, the carburated hydrogen which is being generated combines with the air entering through the grate. At a high temperature this combination is burnt up, whilst the coal from which the gas is partly extracted is consumed in the shape of coke. The inconvenience of the generation of smoke immediately after the supply of fresh fuel, and which it is impossible to avoid in a furnace of ordinary construction, is obviated in the "dike" furnace immediately after firing, provided care is taken that the coal resting on the grate is piled obliquely against the partition wall. If this precaution is taken, the part of the furnace intended for the distillation of the coal and the firing-chamber proper, with the flues, are separated by the glowing wall. The hydrocarbons can thus be freely generated, and, instead of being drawn away from the furnace, are carried right through it. Such portions of them as may have escaped are caught up and carried forcibly into the furnace, where, being still more highly heated and brought into contact with the outer air, they are completely consumed by combustion. By this method of burning coal, the consumption of smoke has been fully accomplished; and therefore a great stride towards the solution of this important problem has been made by Herr Wilsmann's arrangement.

In principle, the "dike" furnace corresponds exactly with that of the generator furnace as employed in the heating of gas-retorts, where the hydrocarbons generated from the fresh coals charged into the furnace are forced to pass through the layers of glowing coke. In each case carbonic acid is produced at the outset of the firing. In passing through the glowing coke, this compound, in consequence of coming into contact with the fresh carboniferous material, is reduced to carbonic oxide, which is burnt into carbonic acid if there is a sufficient supply of air. Numerous attempts have been made to apply generator firing to steam-boilers; but hitherto without success. Either the arrangement has been found to be too costly, or other difficulties have arisen involving heavy pecuniary sacrifices, though they might perhaps have offered the slight compensation of a partial consumption of smoke. For this reason it must be readily admitted that the simple method of consuming smoke which has just been described, must be attended with great success if properly carried out. If any proof is needed, it is supplied in the fact that upwards of 600 furnaces on the Wilsmann system have been in operation for some years past in all kinds of works in the Rhenish provinces, in Westphalia, and in South Germany; and that from all quarters, without exception, the most favourable testimonials have been received, not only with regard to the abolition of smoke, but also to the important saving effected

in coal, amounting to from 15 to 30 and even 40 per cent. on the consumption by the old systems.

The author concluded by giving the results of some trials made with a horizontal Cornish cylindrical boiler furnished with an ordinary grate, and subsequently with the same boiler fitted with the Wilmsmann arrangement. In the former case, 1 kilo. of coals evaporated 6.13 litres of water having a temperature of 0° C. (32° Fahr.) at atmospheric pressure; in the latter, 1 kilo. of coal evaporated 8.87 litres of water having a temperature of 0° at atmospheric pressure. The evaporation per hour was found to be 275.7 litres; the evaporation per hour per square metre of heating surface, 15.3 litres; the hourly evaporation per square metre of grate surface, 458.5 litres. By the employment of Wilmsmann's method instead of the old grate firing, a saving of about 30 per cent. in coals is obtained, simply because the consumption of smoke is rendered perfect.

At the close of the paper, a short adjournment took place. On the resumption of the proceedings,

Herr Viehoff, of Saargemünd, related his latest experiences in the employment of wrought-iron tanks for gasholders. In response to his invitation, Herr Blum, of Berlin, informed the meeting that the iron tanks for the holders constructed of late according to the plan of Professor Intze* had answered the purpose perfectly well, and adduced the following instances where the system has been adopted with equally favourable results:—Telescopic holders at Charlottenburg, 10,000 cubic metres capacity; Wurzen, 2100 c. m.; Frankfort, 1000 c. m.; Liegnitz, 3000 c. m.; Bernburg, 2000 c. m.; Freiberg, 2000 c. m.; Hamm, 1500 c. m.; Fürstenwalde, 1000 c. m. Single-lift holders: Spandau, 2500 c. m.; Göttingen, 2000 c. m.; Emmerich, 2000 c. m.; Marienburg, 600 c. m.; Borna, 600 c. m.; Konitz, 400 c. m.; and Burgstädt, 400 c. m. In addition to the foregoing, there have been constructed a telescopic holder at Chemnitz, with a capacity of 7000 cubic metres; two telescopic holders at Plauen, each of 300 cubic metres capacity; and the following single-lift holders:—Two for Guayaquil (Ecuador), each 2000 c. m.; one for Bienne, of 2000 c. m.; one for Lüben, of 600 c. m.; one for Lauscha, of 600 c. m.; one for Oberursel, of 130 c. m.; and two for Terni, (Rome) of 100 c. m. and 50 c. m. respectively. Well-executed photographs were shown of the holders at Charlottenburg and at Spandau. The speaker proved conclusively that with holders constructed according to Intze's system, the outward thrust of the soil is so completely counteracted that it may be disregarded, and only the vertical pressure upon the foundation considered. Attention was drawn to the connection between the guide-framing and the tank itself, which is arranged so that even the greatest pressure of wind on one side of the structure would not affect, to a marked extent, any particular parts, since the whole wind pressure is transferred to the solid rest-ring. Consequently, there is nothing to prevent the construction of three-lift and even four-lift telescopic holders with tanks on Professor Intze's plan. The advantages of the Intze tank consist mainly in this—that all the parts of the entire structure are readily accessible and easy to examine. Destruction of the lower portion by rust is therefore easily prevented by applying an occasional coat of paint. In reducing the bulk of water to half the usual quantity, the foundations (which consist only of a ring of cement masonry) have but little weight to bear. At Charlottenburg this weight amounts to less than 2 kilos. per square centimetre; and even this can be reduced still further by making the ring wider, so that it is possible to build upon the most unfavourable soil. It is further requisite to utilize as much as possible the space under the dome, which takes the place of the usual earth cone. At Charlottenburg, for instance, this space is 32 metres wide, and is used for storing retorts, fire-bricks, tubes, chandeliers, &c. The space is lighted by means of windows in the daytime, and at night by the aid of lamps from the outside; the warming being done by a steam-pipe carried round the structure. To the foregoing advantages must be added that of rendering the inlet and outlet pipes more easily accessible than they are with ordinary gasholders. In conclusion, the speaker explained the arrangements for heating the water in the tank during the prevalence of inclement weather.

In the course of the discussion which followed, Herr Erpf (Pforzheim) confirmed the statements made as to the good results to be obtained by the adoption of Professor Intze's idea, and only complained of difficulty experienced in connection with heating with underground water. Herr Morz, of Carlsruhe, on the other hand, maintained that very good results had been obtained at his works by heating with underground water at a temperature of 8 to 10° C. Herr Kugler (Offenbach) alluded to the heavy expense which the application of the Intze system involves, and to the difficulty of making a good foundation for full-sized tanks, so as to protect the bottom effectually against rust. He admitted, however, that the danger of rust was not so great as altogether to stand in the way of the adoption of the system. Herr Pechner (Ludwigshafen) closed the discussion by making some very favourable remarks both as to the durability of the Intze tanks and the facility with which they could be constructed.

The next subject introduced was the question, "Can the Butzke lamp be recommended for intense lighting?" by Herr Kugler (Offenbach), who stated that he made numerous experiments both

with this and the Wenham lamp, and found that the latter generally burnt with an unsteady light, instead of with a round, even flame, whilst his experience of the Butzke lamp was that it gave a very steady light. Herr Dr. Götzke (Berlin) pointed out that the flame of the Wenham lamp burnt from within outwards, whilst the Butzke lamp burns in an opposite direction. The consequence is that the tops of the flames disappear in the central mass, as in all inverted burners; whereas in the Wenham lamp the jagged points are bound to remain visible to the eye. The President mentioned, as an advantage, that the Butzke lamp produces a pure white light; whilst the Wenham lamp burns with a yellowish flame.

The next subject to occupy attention was: How can the lead packing used in pipe-joints best be prevented from being driven out by the high pressure of water or of any other force? On this point Herr Reuther (Mannheim) remarked that the best means of preventing the displacement of the packing, even under a high pressure, was the widening of the inner end of the socket. The President stated that the displacement of a lead ring under a pressure of 18 atmospheres had occurred to his own knowledge; and he suggested that it might be prevented by the application of a concave mould in the interior of the socket, which, however, should be constructed in such a form that the mould in fitting the lead mortice, should not be sheared off. Herr Blum (Berlin), on the other hand, did not consider the use of socket-pipes at all advisable at so high a pressure; and he recommended the employment of flange-pipes instead.

At the conclusion of the technical portion of the proceedings, Herr Lux (Ludwigshafen) explained his gas-balance by the aid of a model, and expressed a hope that it would prove of great assistance in experiments connected with the testing of gases produced from different kinds of coal.*

A vote of thanks was then passed to those who had introduced subjects for the consideration of the meeting, or taken part in the discussions, and the meeting broke up.

The following morning was profitably employed in a visit to the pumping station and the high reservoir of the Municipal water-works at Ludwigshafen, where an excellent sample of Wilmsmann's smoke-consuming furnace was seen in operation. A hurried inspection of the gas-works, and of the local organ-building establishment was followed by an excursion by train to Marbach, Schiller's birthplace; and a pleasant *réunion* of the members in the evening brought the meeting to a close.

THE HALIFAX GAS COAL CONTRACTS.—It has been intimated that the Sub-Committee of the Halifax Corporation appointed to consider the recent correspondence between the Town Clerk and Mr. Ellis Lever, Mr. Thomas Fox, and the Editor of the *Pall Mall Gazette*, with power also to take such steps as they might think expedient with the object of bringing about a satisfactory investigation of certain charges in reference to contracts, will make a report to the Town Council to-morrow (Wednesday), when the usual meeting of the Council will be held.

PRESENTATION TO MR. J. DIGGS, OF NOTTINGHAM.—Last Saturday week, the *employés* at the Basford works of the Nottingham Corporation Gas Department met at the Clinton Hotel for the purpose of presenting Mr. J. Diggs, the Deputy-Manager of the works, with a substantial token of their regard, on his leaving England for Buenos Ayres, at which place he has accepted a similar position under Mr. L. T. Wright. The presents consisted of an elaborate marble timepiece, a silver teapot, and a magnificent set of lace curtains—the latter being the gift of Mr. C. Hardy, of Nottingham, and intended to remind Mr. and Mrs. Diggs in their far-off home of the affection displayed to them by all who knew them in the town. The chair was taken by Mr. Wilkinson, the Manager of the Traffic Department; the vice-chair being occupied by Mr. West, the foreman fitter—both of whom alluded, in touching terms, to the sorrow and regret felt by all in parting from Mr. Diggs, in whom they had always found a kind and cheerful master, and who, while a strict disciplinarian and firm administrator, yet always lent a willing and sympathizing ear to the troubles of his men. Mr. Diggs, in reply, thanked them all for their beautiful and costly presents; saying he could assure them he valued them, not only for their intrinsic value, but as showing the spirit in which his friends regarded him. He was told that out of a total of 120 men at present engaged on the works, 110 were subscribers; and this fact was a source of great satisfaction to him. Wherever in the future fortune might place him, he should always think with affection of the hands at Basford. He trusted they all would do their utmost to maintain the efficiency and good manufacturing results they were now obtaining. Many of them would remember the poor results of carbonization before the advent of Mr. Wright, who came (almost simultaneously with himself) from Beckton to Nottingham. At that time it was with the greatest difficulty that 9800 cubic feet of gas per ton of coal carbonized could be obtained; with a mouthpiece delivery of about 4800 or 4900 cubic feet. Now, however, with inferior coal to that previously used, they were producing 10,700 cubic feet per ton; whilst the mouthpiece returns were over 6000 cubic feet, and the illuminating power was more than 19 candles. The remaining part of the evening was spent with glee-singing; the proceedings terminating with enthusiastic cheers for Mr. and Mrs. Diggs.

* The system of gasholder construction devised by Professor Intze was described in a paper presented by him to The Gas Institute in 1885; and it was subsequently dealt with in articles which appeared in the *JOURNAL* on Sept. 15 and Oct. 20 of that year (pp. 457, 685.)

* The latest forms of this instrument were brought under the notice of The Gas Institute by Herr Lux at the recent meeting.

A NEW PROCESS FOR THE MANUFACTURE OF SULPHATE OF AMMONIA.

In the abstract of the papers read at the last congress of the Société Technique du Gaz en France, which appeared in the JOURNAL for July 24, notice was taken of the communication made to the members by M. de Lachomette, on the subject of his new process for the manufacture of sulphate of ammonia. As this paper was regarded as one of the most important of those presented to the meeting, it may be of interest to amplify our previous notes by the aid of the full text of the paper, which was given in a recent number of the *Journal des Usines à Gaz*.

The author began by stating that about two years ago he set before himself the problem of dispensing with sulphuric acid in the manufacture of sulphate of ammonia; being of opinion that the attainment of such an object would be attended by many advantages. After making a number of experiments, he thought he had solved the problem from a commercial point of view. He came to the conclusion that the coal itself (or, more correctly speaking, the oxide of iron which has served for the purification of the gas) would furnish the sulphur which, in combination with the oxygen of the air and subsequently with ammonia, is required for the production of sulphate, and that there could be obtained in this way a salt of which all the constituent elements would be derived from the coal. His first idea was to convert the sulphur of the coal into sulphuric acid, with the intention of subsequently manufacturing sulphate by the ordinary process. This plan, however, was soon abandoned, owing to the outlay necessary for the installation of the plant, and the difficulties attending the manufacture of sulphuric acid on a small scale. But the question arose as to whether these difficulties could not be surmounted by the employment of sulphurous acid, produced by the burning of sulphur, in the formation of sulphate of ammonia capable of being used directly in agriculture as a nitrogenous ingredient in the making of manure, or of being easily converted into ordinary sulphate of ammonia.

It was in consequence of noticing the heavy vapours of sulphite of ammonia produced by the combination of the sulphurous acid escaping from the test-vessels used in the manufacture of sulphuric acid with the ammoniacal vapours from a neighbouring alkali vessel, that the author's attention was first turned to this matter. These very heavy vapours formed upon the soil a kind of dense cloud, and the idea of condensing them was perfectly natural; but all kinds of appliances were brought into use for the purpose, but without success. Recourse was then had to the wet process, by passing into a vat containing water a current of ammonia and gaseous sulphurous acid, in the proportions required for the production of sulphite of ammonia. When the liquor had become saturated, the salt formed was deposited at the bottom of the vat, precisely as in the manufacture of sulphate; but this method presented many difficulties. In the first place, it was necessary to regulate with great care the proportion of the two gases—a by no means easy matter; then frequent obstructions occurred in the pipe conveying the ammonia.

A very interesting observation started the author on a fresh track. While working the foregoing method, he happened, without at first noticing it, to use an excess of sulphurous acid. The liquor in the vat, which ordinarily indicated 27° Baumé (1·216 sp. gr.), and which crystallized, went up to 34° or 36° Baumé (1·288 or 1·310 sp. gr.), and all the crystals disappeared. Though perplexed at first, he soon ascertained that bisulphite of ammonia had formed, and that this salt was much more soluble than sulphite. This difference in solubility between the two salts, the author proceeded to turn to account. The sulphite liquors, which he obtained in the manner indicated above, were treated simply with sulphurous acid, and converted by a continuous process into bisulphite liquors. These, being collected in crystallizers, were afterwards treated with a current of ammonia, by which they were converted into sulphite. This reaction was accompanied by a great increase of temperature; and when the liquid cooled again, a very considerable deposit of salt was produced. The mother liquors were then treated again with sulphurous acid, and afterwards with ammonia; these two operations being repeated successively. Before saturating the bisulphite with ammonia, it was found to be indispensable to add to it the quantity of water necessary for the crystallization of the salt to be formed, in order to preserve for the succeeding operation the original volume of mother liquor, which otherwise would tend to gradually diminish. It was easy to determine this volume, either by calculation or, more simply, by experience.

The following are the formulæ of the reactions which take place in the operations above described. The formula for sulphite of ammonia is—

By adding sulphurous acid (SO_2), we get—

Adding ammonia and water to the bisulphite formed, we have

Theoretically, the bulk of liquor at the end of the operation will be exactly what it was at the outset, provided, be it understood, that the temperature is kept equal. For example, if a volume of liquor containing in solution a certain equivalent of sulphite—say, 67 kilos.—is treated, there will be found in the vat, in a state of crystals, the same quantity of salt. In practice, however, the amount of salt deposited will be less, because it is difficult to completely saturate the sulphite by sulphurous acid; but it is amply sufficient for satisfactory working on a commercial basis.

Here, then, we have a practical process for the manufacture of

sulphite of ammonia on a large scale. In order to arrive at the complete solution of the problem which the author set himself, it is of course necessary to convert this salt into sulphate. This can be effected by the simple exposure of it to the air; but in that case a great deal too much time is needed. He asked himself if, in depriving the sulphite of one of its equivalents of water, the equivalent of oxygen necessary to transform it into sulphate would not be fixed more rapidly. This was found, on trial, to be correct; and under these conditions oxidation was effected in a few hours instead of requiring weeks. The reaction is very quick, and may cause a rise of temperature to the extent of 100° C., which has to be avoided in order not to cause the decomposition of the salt. It is very easy to moderate this re-action by working in a confined space, and regulating the admission of air.

The author remarked, in conclusion, that he only wished to indicate the theory of these new manufacturing processes; reserving for some future paper the description of the apparatus to be employed, which was being somewhat modified. At the same time he thought he was in a position to state that this manufacture would henceforth require only simple appliances easy of manipulation, and comparatively inexpensive to set up; and their cost would be covered by the value of the oxides of iron resulting from the roasting of the spent purifying material for the production of sulphurous acid. Some trials were made of the sulphite for agricultural purposes, as compared with the sulphate manufactured by the ordinary processes; and the sulphite stood the test well. These experiments have just been confirmed by the results obtained by authorities more skilled than the author in matters of agriculture; and further experiments are now being carried out at certain agricultural stations. He considers that manufacturers will confine their operations to the production of sulphite of ammonia by the method indicated, and that it will be in this form that the ammonia resulting from the carbonization of coal will in the future be disposed of for agricultural purposes.

WOODEN WATER-PIPES.—At the meeting of the Newcastle Society of Antiquaries last week, one of the members presented some pieces of wooden pipes that were recently discovered in the Side, while some new telephone lines were being laid. They were made of elm, and illustrated two methods of joining pipes. There was, in one method, a butt joint, which was made water-tight by an iron ferrule. There was also the spigot and faucet principle; a pointed end fitting into a cup-shaped socket, fastened with a pin. It was mentioned at the meeting that in 1698 an Act was obtained to supply the town with water; and 4-inch pipes were put down from the Town Moor and across to Gateshead. It was believed by some that these were part of the water-pipes used.

PRESENTATION TO MR. J. C. INGHAM.—The retirement of Mr. Joseph C. Ingham from his position on the staff of the Bury Corporation Gas Department was taken advantage of by the *employés* at the works to signalize the friendly relations which have for so long a time existed between them and their late Assistant Manager, by presenting him with a handsome black marble timepiece, inscribed as follows:—"Presented to Mr. Joseph C. Ingham by the Engineer and general *employés* of the Bury Corporation Gas-Works, on his being appointed Manager of the Ramsbottom Gas Company, as a small token of their esteem and well wishes for the future." The presentation took place after a dinner at the Dun Horse Hotel, Elton. Mr. William Woodward, the Engineer and Manager of the gas-works, occupied the chair. After the usual loyal toasts had been honoured, he proposed the "Health of Mr. Ingham," and called on Mr. John H. Walker, the foreman, to make the presentation on behalf of the men. Mr. Ingham received the present amid applause, and appropriately responded to the toast bearing his name.

ENGINE INDICATORS AND DIAGRAMS.—Mr. W. W. Beaumont, M. Inst. C.E., has just edited and enlarged in book form a series of articles on this subject that appeared a short while ago in the pages of the *Electrician*; his work appearing under the comprehensive title of "A Practical Treatise on the Steam-Engine Indicator and Indicator Diagrams," and containing some notes on steam-engine performances, on the expansion of steam and the behaviour of steam in the cylinders of steam-engines, and on gas-engine diagrams. The author declares his intention in preparing the book to have been "to place in the hands of students and practical men a concise guide to the objects, construction, and use of the indicator, and to the interpretation of indicator diagrams." The plan of the work is first to consider the object sought for in the preparation of indicator diagrams—what it is desired shall be shown by them. The construction of the various forms of apparatus devised for the purpose, their attachment to the engine, and the manner of their use form the next section of the book; followed by examples of diagrams for engines most in use, with an interpretation of them, so as to show how far they agree with theoretical diagrams. The author also gives simple methods of calculating and constructing theoretical curves of expansion, and of comparing the actual with the theoretical performance of steam in particular forms of steam-engine cylinders. In order to render the book useful to practical men, arithmetical treatment of figures has been adopted throughout. A special chapter has been devoted to gas-engine diagrams; the types being those singled out by Mr. Dugald Clark in the course of his investigation—the Lenoir engine, the Simon engine, and those of the Otto, Clerk, Atkinson, Beck, and Griffin type.

Register of Patents.

GOVERNORS FOR STEAM, GAS, AND OTHER FLUIDS AND LIQUIDS.—Parkinson, F. B., of Bury, Lancs. No. 10,853; Aug. 8, 1887. [6d.]

This invention consists in enamelling with vitreous enamel the metal surfaces of the diaphragm chambers of governors, and any other portions where desirable; the object being to prevent any possibility of corrosion through exposure of the parts to damp and moisture.

REGENERATIVE GAS-LAMPS.—Clark, F. W., of Upper Ogle Street, London. No. 13,120; Sept. 28, 1887. [8d.]

The object of this invention is to ensure the steady burning of regenerative gas-lamps in strong currents of air.

In the illustrations, the burner and the passages by which the air for supplying the flame is heated by the escaping products of combustion passing up into the chimney, are arranged as in the Wenham lamp. The chimney is surrounded by a casing D, of such a diameter as to leave an air space between its inner side and the exterior of the chimney. The casing communicates at its lower end with the lower hood E, into which air enters by the perforations to supply the flame by passing through the channels of the heater. The upper end of the casing opens

Fig 1

Fig 2

into the chamber F, into which the upper end of the chimney also opens, as shown. This chamber has perforations in its top and bottom; the upper ones being covered by a hood formed in one with the top cover or cap H of the lamp. Perforations are also made in the lower part of the casing; and the two sets of perforations have opposite them (inside the casing D and hood E respectively) deflectors, which direct the air entering the perforations upwards, so that any excessive amount of air due to sudden gusts of wind will not enter directly into the tubes of the heater and impinge on to the flame, as the surplus beyond that required for the flame passes upwards, and finally escapes with the products of combustion through the perforations in the chamber F. This controls and ensures the proper and regular flow of air to the flame caused by the draught in the chimney.

In some cases—more particularly in lamps of large size—in place of, or in addition, to the perforations in the chamber F, there is (as shown in fig. 2) a series of perforations in the cap H, with a weather guard above the opening. This guard (opposite the perforations) may also be perforated; as this, says the patentee, will be found to be a ready means of regulating the air supplied to the flame.

GAS-LAMPS, BURNERS, AND SHADE-CARRIERS.—Kennedy, W. W., of Edinburgh. No. 16,276; Nov. 26, 1887. [11d.]

This invention relates to an appliance to be attached to an ordinary wall gas-bracket, or to the bracket or arm of a centrally-suspended gasolier, having within it an annular passage for heating the gas, extending vertically upwards above the burners, and so that a portion of the heat escaping from the burners is caused to gradually heat the gas on its travel through the annular passage towards the burners.

Fig 1

Fig 2

The apparatus shown in fig. 1 is attached by the screw socket A to the screw on a wall bracket or on the branch of a gasolier, whereon the gallery for carrying the shade is usually attached. The gas, as it passes the tap, ascends through the central pipe B, until reaching the upper part, when it descends in the annular space C contained between the

inner pipe B and the outer pipe D. On arriving at the bottom of the passage C, the gas has become heated by the flames issuing from the burners E; and in this heated state it escapes into the passage F, and thence to the burners.

For the purpose of carrying the glass shades used with the burners, the gallery consists of the central piece and arms G shown in fig. 2, to be carried at the upper part of the tube D. From this arrangement it will be seen that the glass H is suspended over the burners E by its other end resting upon the points of the three arms G. This arrangement not only gives complete support to the shade, but admits of it being moved without difficulty for the purpose of being either cleaned or replaced.

APPLICATIONS FOR LETTERS PATENT.

12,273.—LAWRENCE, J., "A new or improved device for stopping leakage in hose and other pipes." Aug. 25.

12,281.—CUNNINGHAM, J., "Improvements in machinery or apparatus for charging gas-retorts." Aug. 25.

12,283.—WILSON, C. C., "Improvements in gas-stoves." Aug. 25.

12,313.—BOSSHARDT, F., "Improvements in apparatus for detecting and announcing the presence of explosive gases in mines or other places." A communication from Molas, J. Aug. 27.

12,318.—JARDINE, J., and FERGUSON, J., "Improvements in and relating to gas and air reversing valves for regenerative, smelting, and other furnaces or purposes." Aug. 27.

12,370.—WILLIAMS, S. DE LA GRANGE, "New or improved burners for heating lime-kilns, and brick and other kilns by the combustion of gas, and for other like purposes." Aug. 28.

12,399.—CHARON, L., "Improvements in gas motors with variable expansion." Aug. 28.

12,467.—BIDDISON, S. M., "Water and oil gas machine and burner." Aug. 30.

8080.—LEONI, S., "Gas-ovens."

8110.—REDMAN, T., "Mercurial gas governors."

WEST KENT GAS COMPANY.—The Directors of this Company report that there has been a slight increase in the sales of gas during the half year ending June 30 last; and they think that there is a probability of a further increase in consumption, owing to the introduction of new industries into the district. The residua have realized better results. Referring to the public lighting of Erith, they say that the lamps are now being experimentally lighted with oil; and even if this mode of lighting can be adhered to, they do not anticipate that it will materially influence the dividend, as the profits on public lighting are small. The total receipts in the half year amounted to £7329 9s.; and the expenditure to £4333 18s. The Directors recommend the payment of the statutory dividends.

HARROGATE GAS COMPANY.—The half-yearly meeting of the shareholders of this Company was held on Thursday last. The interim statement of accounts was read by the Secretary (Mr. P. H. Wilkinson). This showed a profit of £3267 7s. 4d., which, with the addition of the balance brought forward, left an amount available for dividend of £4046 13s. 9d., out of which (after the preferential charges were met) the Directors recommended the payment of an interim dividend of 7½ per cent. on the "A" stock, £5 12s. 6d. per cent. on the "B" stock, and 5½ per cent. on the "C" stock, leaving a balance to carry forward of £966 12s. 8d. The Chairman called attention to the fact that, notwithstanding a reduction in the price of gas of 3d. per 1000 cubic feet in January last, the net profit of the half year was about £500 in advance of the corresponding portion of the previous year; and he anticipated, if the Harrogate season is not materially injured by the unfavourable weather, a further reduction in price may be made in 1889. He considered that the advantages of the sliding scale, when properly and judiciously developed, were of equal benefit to stockholders and consumers. For example, in 1881 the Company's "A" stock was selling at 177½, and the "B" at 148. The price of gas had been reduced 1s. 6d. per 1000 cubic feet; and at a sale by auction recently, the same stock realized 327 and 237 respectively. He was also pleased to state that the Company were in thorough accord with the local authorities; and complaints from the consumers were comparatively speaking unknown, as the Company's officials educated their consumers in utilizing gas to advantage. The recommendation of the Directors was adopted, and a dividend declared in accordance therewith. The meeting closed with a unanimous vote of thanks to the Chairman, the Directors, and the Engineer.

COMPLETION OF NEW FILTER-BEDS AT DEVONPORT.—Two new filter-beds in connection with the Devonport Water Company's reservoir at Crownhill have recently been completed, and are now in use. They are situated to the north of Crownhill Fort, and are about a ½ mile from the Company's filter-beds at Brooklands, which were completed in 1877. Since then there has been such a large increase of population, and a consequent additional demand for water, that further works were necessary. The new beds were commenced in November, 1886; and it is expected that these increased filtering facilities will meet the Company's requirements for about ten years to come. The work just completed consists of two filter-beds, each 115 feet long, 80 feet wide, and 8 feet deep; a pure-water tank 80 feet long, 20 feet wide, and 9 feet deep; a gauge tank; and a service of 20-inch cast-iron pipes, connecting the beds with the mains at Brooklands. Both the old and the new filter-beds are connected with the Crownhill reservoir by 15-inch cast-iron pipes. The area of each of the new beds is about 1000 yards; and each bed is capable of filtering about 500,000 gallons of water per day, equal to about 500 gallons to each superficial yard. In each bed there is a depth of about 4ft. 6in. of filtering materials; the top 18 inches consisting of clear silicious sand, brought specially from Bridport, and which, before being placed in position, was carefully washed in machines provided and fixed in the centre of each bed for the purpose. The filtering material, which amounts to about 3000 tons, was washed and put in place by the Company's own staff. The chief Engineers were Messrs. T. and C. Hawksley; the progress of the work, which has cost several thousand pounds, being watched by Mr. H. Francis, the Company's Resident Engineer. The Contractor for the excavations, draining, and masonry, was Mr. G. Shillabeare, of Plymouth.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

MR. CARPENTER ON GASEOUS FIRING.

SIR,—Your correspondent, “Jocelyn Cruikshank,” has misread my letter of July 28. By coke sold, I meant the quantity sold to, and paid for by, consumers per ton of coal carbonized; and the figure given, of course, represents that available after the work’s consumption for steam-raising and other purposes besides retort heating.

As “Jocelyn Cruikshank” very truly says, there cannot be much difference in the weight of the residual coke left behind in the retort after carbonizing a ton of coal in either of the places mentioned in his letter. Surely then, “coke sold” is a better indicator of real work’s economy than figures dependent on assumptions of production discordant in the highest degree, as “Jocelyn Cruikshank” well points out.

In conclusion, I am confident that, despite “Jocelyn Cruikshank’s” evident penchant for a scientific regenerative furnace, he would be the last person to affirm that a scrap of value attaches to any of the patents for “regenerators” themselves—certainly a not unimportant consideration in the economic construction of carbonizing plant.

Sept. 1, 1888.

CHAS. C. CARPENTER.

THE METROPOLITAN GAS COMPANIES.

SIR,—Though not a gas engineer, I have for some years past taken great interest in the working of the three great Gas Companies which share the monopoly of the London Gas Supply, and in the proceedings at their general meetings. More particularly, as a statistic, I am in the habit of scrutinizing the statements made as to financial results.

The Governor of The Gaslight and Coke Company, as is well known, is accustomed to treat the proprietors, in general meeting assembled, to a review of the figures contained in the half-yearly statement of accounts. At the last half-yearly meeting of the Company, held on Aug. 10, Colonel Makins gave, among other statistics, the figures relating to the net cost of coal, showing a reduction, which he said was “the largest reduction I ever recollect in a half year.” It is fairly presumable that the Chairman of an important public Company—certainly the largest, “the premier,” of its kind in the world—when he makes a deliberate statement of this sort at the shareholders’ meeting, speaks from information, and knows what he is talking about. I have worked out all the details; and I think that the proprietors of the Chartered Company—who, as a matter almost of course, accept the Chairman’s words as “gospel”—will perhaps be surprised to learn that the said reduction in the net cost per ton of coals for the half year ended June 30 last, as compared with the corresponding period of 1887—viz., 10·44d.—though large and satisfactory, had previously been exceeded, and that considerably and so recently as in the half year immediately preceding (ended Dec. 31 last), as well as in the half year ended the 30th of June, 1887, with which comparison was made.

The following tabular statement contains the net cost of coal per ton for the five half years here brought into comparison, and the several decreases referred to, as well as the rate or percentage of decrease:—

Particulars.	Half Year ended				
	1886.		1887.		1888.
	June.	Dec.	June.	Dec.	June.
Net cost of coal, per ton . .	d. 78·55	d. 76·08	d. 63·82	d. 62·54	d. 53·38
Decrease on corresponding period of previous year, per ton	—	—	14·73	13·54	10·44
Rate of decrease, per cent. .	—	—	18·76	17·80	16·35

Among meaner mortals, such an oversight or error would go far towards convicting a speaker of ignorance and incapacity in matters within his own cognizance. Seeing that Colonel Makins was so singularly and utterly oblivious of a not unimportant detail in the working during the past two or three years of the Company which is his especial charge, he can hardly be expected to know or care to know that the decrease which he deemed unprecedented had, also recently and largely, been exceeded by his immediate and nearest rivals—the South Metropolitan Gas Company, as under:—

Particulars.	Half Year ended			
	1886.		1887.	
	Dec.	June.	Dec.	June.
Net cost of coal, per ton . .	d. 58·54	d. 59·65	d. 46·15	d. 41·91
Decrease on corresponding period of previous year, per ton.	—	—	12·39	17·74
Rate of decrease, per cent. .	—	—	21·16	29·74

In this connection, I may also further note that in the two consecutive half years ended June 30 and Dec. 31, 1884, the decrease in the net cost of coal to the South Metropolitan Gas Company was, respectively, 23·46 and 24·59 per cent.; also that the Commercial Gas Company’s accounts showed decreases, in the net cost of coal, of 22·35 per cent. in the half year ended Dec 31, 1884, and of 20·12 per cent. in the half year ended Dec. 31, 1886.

It may—it no doubt will—be said, in reply, that the Chairman is not expected to speak on technical matters as an expert therein; and that all such figures are to be taken *cum grano salis* as mere figures of speech. Against that, however, I would urge that I have in my mind the case of at least one Chairman, if not more than one, who makes it his business to understand and to speak of all such details with knowledge, and therefore correctly. But it is still more cogent to remark that these are

not technical matters of working at all; but are mere questions of treating the resulting figures by the four plain and simple rules of arithmetic, and quite within the competency of the Board-scholar of the period.

Moreover, these statistics are put forth on authority, as fixed standards for comparison, from year to year. If the Chairman is to be regarded as a mouthpiece merely, the responsibility for their accuracy is only shifted one stage farther back, where it will assuredly press with still greater weight.

The discrepancies which I have pointed out are so startling that I trust you will accord space in your columns to this expression of the views of one who—beyond paying his gas-bill to a Suburban Gas Company—has no connection whatever with the Metropolitan Gas Companies, and is therefore impartial and independent.

Aug. 31, 1888.

OUTSIDER.

MR. KEY’S NORTH BRITISH ASSOCIATION PAPER.

SIR,—In your issue of the 28th ult., in the paragraph immediately under the heading, “Mr. Key’s Paper,” I am made to say, “The effect was to put out the gas.” I said no such thing. What I did say is quoted in my paper, reported near the bottom of the second column of page 291 of the JOURNAL for Aug. 14—namely, “The flame of gas has almost entirely lost its luminosity, although the shape and size of the flame remains as large as before.”

My remarks on Mr. W. Young’s very valuable paper on the subject of gas and oil contact, read before the West of Scotland Association, and reported in the JOURNAL for Oct. 27, 1874, have been entirely omitted from your report of my remarks. I have frequently verified Mr. Young’s experiments, and proved for myself the destructive effect of hydrocarbon oils or gas at low temperatures. I may mention that the temperature of the air of the lecture hall in which I read my paper was found to be 68° Fahr., which in my experience quite justified the result of the experiment, and proved my reason why the temperature of all apparatus in gas-works should be maintained at 60° in winter.

I showed a sketch of my apparatus, to extract the tar by striking the gas by revolving fans, to Mr. Alex. Black, Manager of the gas-works at Alexandria, N.B., 17 years ago.

Exception was taken to my paper from the fact of its being of a theorizing nature, and for not having brought it forward before. I may perhaps be allowed to know best when is the time to bring forward my plans or theory; and this I thoroughly explained to the meeting, but it also is entirely left out of the report. Valuable papers have been, from time to time, read before the members of The Gas Institute, which were wholly hypothetical in their character; and they were discussed then much in the same spirit in which the authors brought them forward. The authors received condemnation from no one. The most recent case is the question of gasholders without guide-framing. There was, in that case, not even the desired ounce of fact, and very likely, but for the theorizing advanced on paper, Mr. Geo. Livesey may not have had the honour of being the first to put it into practice at Rotherhithe.

The remainder of the President’s remarks on my paper, I will not take any notice of, further than to say (quoting him), “It would have been far better if it had never been said;” and especially in this case, that the Revision Committee had exercised more discretion than to have publicly reported them.

Glasgow, Sept. 1, 1888.

WILLIAM KEY.

THE DARWEN NEW GAS-WORKS.—At the meeting of the Gas and Water Committee of the Darwen Town Council on Monday afternoon of last week, it was reported that the new gas-works were in an advanced state; and that probably in a fortnight’s time the manufacture of gas would be commenced there. It was also stated that the supply of gas had gone up 20 per cent. during the month.

NEWPORT (MON.) WATER-WORKS COMPANY.—The final half-yearly meeting of this Company was held yesterday week. In moving the adoption of the report, the Chairman (Mr. J. Lawrence) referred to the acquisition of the undertaking by the Corporation. He expressed the regret of the Directors at parting with the property; but said he hoped the transfer would be for the benefit of the town at large. The usual maximum dividends would be paid, and the new annuities created by the transfer would bear interest for the next half year, and be payable on Jan. 1, 1889. The motion was carried unanimously. In the course of the subsequent proceedings, the Chairman remarked that the question as to what should be done with the reserve fund was engaging the attention of the Directors; and as soon as a scheme had been arranged, an extraordinary meeting of the shareholders would be called to consider it. It was impossible at present even to indicate the sum which would be at disposal. Colonel Lyne moved a vote of thanks to the Chairman and Directors, and alluded to the success which had attended the Board in conducting the delicate negotiations with the Corporation. He believed the transfer had been satisfactory to all parties; and said that proof of this was to be found in the circumstance that the new stock was £20 above par. Mr. E. Grove, in seconding the motion, expressed the hope that the old servants would be considered in the scheme for dealing with the reserve fund. The motion was passed unanimously.

WOLVERHAMPTON GAS COMPANY.—The half-yearly meeting of this Company was held last Tuesday. The accounts showed that the receipts for the six months ending June 30 last amounted to £27,904, and the expenditure to £20,637; leaving a net profit of £7,267, which, added to the balance brought forward from the previous accounts, made a sum of £7700 available for division. The dividend recommended would absorb £6392; a balance remaining of £1308. Of this sum the Directors proposed to place £1000 to the reserve, and to carry forward the remaining £308. The Chairman (Mr. J. Underhill), in moving the adoption of the report, congratulated the shareholders upon their improved position, remarking that last year they had to take £1700 from the reserve for the purpose of paying the dividend. The £1000 to be added this half year would make the reserve stand at £3327; but their Act allowed them £5000. When this aggregate had been reached, the Directors would consider the question of reducing the price of gas. Residuals were still below their former value; but they hoped in time to be able to increase the present selling price. The motion was carried; and a dividend of 5 per cent. was afterwards declared upon the consolidated stock, and 3 per cent. upon the preference capital. A vote of thanks was passed to Chairman and Directors; and a similar compliment was paid to the officers, in replying to which Mr. John Annan, the Consulting Engineer of the Company, said that he believed as the price of gas was reduced there would be an increased consumption.

Miscellaneous News.

THE PROPOSED REFORM OF PRIVATE BILL LEGISLATION. THE MINORITY REPORT.

When noticing, in a recent number of the *JOURNAL* (*ante*, p. 214), the proceedings of the Joint Committee of the two Houses of Parliament appointed to examine into the present system of Private Bill Legislation, we stated that, at the conclusion of the Committee's labours, two reports were presented—one drawn up by the Chairman (Lord Monk Bretton), and the other by Lord Balfour of Burley. Both reports were read to the Committee; that of the Chairman being adopted, with some slight modifications, and presented to Parliament. At the meeting of the Committee at which the report was agreed to, the only absentee was Mr. T. Healy; and the final decision in favour of the Chairman's report was come to by a majority of seven votes to four. The voting was as follows:—For: Lord Monk Bretton, Earl Bathurst, Lord Kensington, Sir J. Mowbray, Mr. Craig-Sellar, Mr. Raikes, and Mr. J. Morley. Against: Lord Balfour of Burley, Lord Stalbridge, Lord Colville of Culross, and Sir J. Pease. It will be seen that the representatives of the Upper House were thus equally divided on the question of a commission acting locally; while the members of the House of Commons were four to one in favour of reform. Leaving out Mr. Healy, the solitary exception to the general opinion of the representatives of the Lower House was Sir Joseph Pease, who did not attend any of the sittings of the Committee at which evidence was taken. The text of the adopted report was given in the *JOURNAL* last week; and it may be interesting, in connection therewith, to make our readers acquainted with the views of the minority, as embodied in Lord Balfour's report, by reproducing this document, which was as follows:—

In the earlier part of the inquiry, the Committee directed their attention to the complaints which have been made against the present system of Private Bill Legislation, with the view of finding remedies for them. Incidentally, they heard allusions to the burden imposed on members of the House of Commons by the duty of serving on Private Bill Committees, intensified by the alteration in the hours of sitting and the appointment of Grand Committees; and they were informed of a resolution of a Committee of the House of Commons, that if the House were divided into four Standing Committees, arrangements should be made to relieve the House from the duty now discharged by Private Bill Committees. In reference to this matter, Mr. Stanhope said: "It certainly seemed absolutely impossible, if any of those schemes were adopted, that private members of the House of Commons could continue to sit upon Private Bill Committees; and although, for the present at any rate, those schemes are put on one side, yet I cannot help thinking that even now the enormous demand made upon members of the House of Commons to sit either upon Grand Committees or upon Public Committees, involves such a strain upon them, that it cannot be hoped that for very long they will be able to sit on Private Bill Committees also, especially if, with a revival of trade, there should be, as there probably would be, a large increase in the number of Private Bills."

Towards the end of their investigation, Sir John Mowbray, a member of the Committee, gave evidence to the same effect, but of so emphatic a nature, that it seems right to deal with this point before considering the other matters referred to the Committee. Sir John Mowbray says: "I do not either deny the competence of the Committees, or the satisfaction their decisions give; but I think there must be a change, and that sooner or later Parliament will have to transfer its jurisdiction on Private Bills to some external tribunal." "I find that in each Parliament every year it becomes more and more difficult to man the Committees, speaking from my experience as Chairman of the Committee of Selection;" and, when he is asked, "The consequence is that, owing to those various reasons, the number of members, out of the 676 members composing the House, who are available for Private Bill Committees is very materially reduced?" And again, "It is very materially reduced. And there is another fact I would mention, and that is the altered condition of Parliamentary life. Members go a great deal more into the country than they used to do. They go down to visit their constituencies, to make speeches, to open schools, to open bazaars, and for various reasons; and after they are put on Committees they ask to be allowed to absent themselves for a particular day of the week, or not to be put on until such a time, because they have to go down to meet their constituents. Then when certain members are asked when they will serve, they say, 'July, or late in the Session;' and they send us no reply in many cases. In one Parliament I knew a member who, whenever he was put on the panel or summoned by the Committee of Selection, went to Paris, and telegraphed to us from Paris. We are met with every sort of dodge of that kind. Many members are in London; yet it is very difficult to find them, although they are in London, when they are wanted to serve on Private Bill Committees."

The Committee are of opinion that the question whether a change shall be made in the system of Private Bill Legislation, in order to relieve the House of Commons, is of such great importance, that it should be settled by the House itself, after having been formally discussed. If the House of Commons decide that they are no longer able or willing to find efficient Committees to deal with Private Bills, it will, of course, be necessary to find some other method of dealing with Private Bill Legislation than that which has hitherto been in practice. Subject, therefore, to the opinion that the decision of the House of Commons must settle whether their convenience requires that Private Bills must be removed from the consideration of Committees of Parliament, the Committee believe that they can best serve the object for which they were appointed by considering the question from the point of view of what is most desirable in the interests of the public and the parties to Private Bills. They believe that the value of their conclusions would be diminished if they were affected, or seemed to be affected, by an under current of desire to get rid of an irksome and thankless duty. If not so affected, their recommendations as to the best mode of dealing with Private Bills will be of use when the House of Commons comes to discuss the governing question.

The Committee would press upon Parliament the fact that, though each Private Bill only affects individuals, the sum of Private Bill Legislation is of enormous importance to the commercial interests of the whole country. In connection with Mr. Courtney's recommendation of a Special Commission to deal with Private Bill Legislation, this question was put to him: "There is the immense sum of a thousand millions of money, I believe, already invested upon the faith of the existing Private Bill Legislation. Would you allow your Commission to rip up, if it became necessary, the existing Private Bill Legislation by schemes which impinged upon others which had already been passed by Parliamentary statute?" and his answer was: "I conceive that the Commission would proceed upon the same principles as Parliamentary Committees proceed upon, and I should reserve the last word to either House of Parliament, so that if the Commission became revolutionary either House might interpose. The Commission would, I presume, entertain schemes of competition with existing companies, just upon the same principle as Committees of the House of Parliament do."

It seems only necessary further to add, in connection with this part of the subject, that several suggestions have been made for mitigating the burdens upon members of the House of Commons. For instance, it has been proposed that the number of members of a Committee be reduced to three, and that at the beginning of the session a larger proportion of the total number of Bills introduced should be assigned to the House of Lords than has hitherto been the custom. It should be mentioned that in recent years that proportion has already been increased.

The complaints against Private Bill Committees have come principally, as might be expected, from Scotland and Ireland, and have been chiefly with regard to Bills of a certain type, usually promoted by corporations. The analysis of these complaints shows that the real grievance is almost always the expense caused by Committees sitting at a distance from the localities interested. Almost the only complaint against Committees themselves is contained in the evidence of the Lord Advocate, who says: "I do not know what confidence in the country a Committee of the House of Lords or of the House of Commons commands. I only know that I hear them spoken very much against wherever I go. I know sometimes one Committee decides one way, and another exactly the reverse. Both of these cannot possibly command the confidence of the country generally." This expression of opinion is not borne out by any facts placed before the Committee, and is contradicted directly by the evidence of those who have most experience of the present system. Everyone else, however hostile to its continuance, admits that, so far as the tribunal itself is concerned, it would be difficult to improve upon that afforded by a good Committee of either House; and some recommend the actual transference to the locality of a tribunal composed of the same individuals. It may also be pointed out that every decision is probably regarded with disfavour by one of the parties concerned; and as the one who is dissatisfied probably makes more of his grievance than the individual in whose favour the decision has been given says about the satisfaction with which he regards it, it is not to be wondered at that such feelings as here find expression should have grown up. It is also obvious that if the confidence of the country can only be obtained by a tribunal whose decisions are never reversed, all appeals must be abolished; and this objection applies even to every Court of Law but the ultimate Court of Final Appeal. The Lord Advocate himself gave no examples; but, as an instance of the loose and inaccurate statements which are made on this point, the Committee may refer to the evidence of Mr. J. Wilson, in which he mentions the action of a Committee in regard to a Bill for supplying the town of Falkirk with water, and says that the Bill now before Parliament is "practically the same as the Bill which came before the House of Lords a few years ago." Being questioned upon the subject, he is obliged to admit that the present Bill has nothing in common with the former one except that, like it, it proposes to supply the town of Falkirk with water, but that it does not even go to the same source to procure it. It may be pointed out that but for the accidental knowledge of a member of the Committee of this fact, the complaint made by Mr. Wilson would have been added to the list of grievances laid to the charge of the present system of Private Bill Legislation. The chief complaint of Mr. Beveridge, the Town Clerk of Dublin, appears to be directed against the reversal of the decisions of Committees by the House itself.

It is worthy of remark that no witness from England came before the Committee to complain of the cost of Private Bill Legislation by reason of the inquiries connected with it being conducted in London. With Scotland it was otherwise. Witnesses deputed by the Corporations of Edinburgh, Glasgow, and Aberdeen, and by the Convention of Royal Burghs, urged that much unnecessary expense was incurred which would be saved if these inquiries were delegated to an external tribunal, with powers to conduct them in the localities affected. But there was no uniformity of opinion among these witnesses as to whether the tribunal should sit in Edinburgh, or should hold its sittings in towns and places more nearly interested in the subject of inquiry.

In support of their views in regard to the expense of the existing tribunal, these witnesses produced statements of the costs incurred for a term of years by the corporations which they severally represented. But, so far from justifying the conclusion that the real burden of expense was chargeable upon the London tribunal, these statements showed that it was to be ascribed partly to the expense which must have been incurred before any tribunal, whether local or metropolitan, and in no inconsiderable degree to expenses incurred by the presence in London of deputations and witnesses not always essential to the transaction of the business.

This appears very conspicuously in the statement produced by Mr. Colston of the expenses of "The Edinburgh Extension and Sewerage Act, 1885." Upon the face of this Statement, £1477 12s. was alone applicable to London, while the total charges amounted to no less than £5826 12s. 6d. It is moreover to be observed that the £1477 12s. set down as applicable to London, included the large sum of £257 19s. 6d. paid to the Town Clerk and Deputy Town Clerk for their expenses there, and a further sum of £197 14s. 6d. as the expenses of a deputation to London of members of the Town Council. It is difficult to understand why the presence both of the Town Clerk and Deputy Town Clerk should have been required in London; and though these are in themselves small matters, they show the way in which the present system has been worked by those who are now most forward to complain of the expense of it. On the other hand, the expenses of London professional witnesses of high standing was only £246 15s., an amount obviously very far below what must have been paid to these gentlemen had they been required to go down to give their evidence in Edinburgh. Again, the Parliamentary Agent's professional charges are stated as amounting to only £350, whereas the Town Clerk, who acted as local agent in promoting the Bill, had the sum of £500 paid to him for professional services in London alone, and general business in connection with the Bill. Again, Mr. Berry, the witness for the Corporation of Aberdeen, being asked: "Are any measures taken by the Town Council of Aberdeen to get the allowances made to the deputation taxed in any way?" replied "We are generally pretty liberal in that way; we deal with them generously."

The statement produced to the Committee by Mr. Colquhoun on behalf of the Corporation of Glasgow, when it comes to be analysed, works out in much the same way. Mr. Colquhoun produced a statement showing that the Parliamentary expenses of Glasgow for 10 years from 1872 to 1882 amounted to £108,302; but that statement includes not only the expenses of the corporation as a corporation, but their expenses as owners and promoters of tramways and gas-works, and the supply of water to the city, and a considerable sum incurred in connection with deputations to London on Public Bills. In regard to the cost of promoting and opposing Bills in Parliament, an analysis was presented to the Committee, from which it appears that the Corporation of Glasgow paid for promoting and opposing Bills between 1870 and 1884 inclusive, the sum of £79,546 17s. 6d. Of this sum £10,699 2s. 11d. are stated to be the London solicitors' charges, while the local solicitors' charges amount to £20,821 3s. 9d., or nearly double; £3,383 is charged as deputation expenses (including officials), while the whole cost of witnesses, other than members of deputations, is only £1,803 2s. 3d. House fees about £5,257 19s. 6d.; London counsel's fees, £5,263 5s. 4d; engineers, architects

accountants, &c., £16,279 7s. 9d.; and printing, advertising, lithographing, and miscellaneous, £16,039 7s. 3d. It is obvious that the great bulk of these expenses is not specially due to the fact that Parliament had to deal with the questions at issue. They must have been incurred, whatever the tribunal, or wherever it sat; and if the number and magnitude of the questions dealt with be considered, it is by no means certain that these expenses will not compare favourably with the expenses which would be incurred before any tribunal, legal or other, in which issues equally important would have to be discussed.

The statement produced by Mr. Berry on behalf of the Corporation of Aberdeen, leads to similar conclusions. It is not subdivided so thoroughly as the Glasgow statement; but it shows that the Parliamentary expenses incurred by the Corporation *quâ* Corporation, and as Harbour Commissioners, between 1886 and 1887, were £44,347 7s. 9d., of which £16,483 2s. 7d. were spent in London, that sum covering House fees, fees to counsel, printing evidence, &c. This evidence has, however, to be corrected by the evidence of Sir Theodore Martin, from which it appears that the amounts set down as Parliamentary Solicitors' accounts are in some instances overstated, and in others understated, but with the result, upon the whole, that the London expenses were greatly less than the amount shown upon Mr. Berry's statement. To quote only one instance, Mr. Berry gave the amount of the Parliamentary Solicitor's account, in connection with obtaining the Aberdeen Municipality Extension Act of 1871, at £4664, out of a total expenditure of £8031. Upon inquiry and correction it was discovered that the total account furnished by the Parliamentary Agent to the Corporation in connection with that Bill amounted to £2919, of which £1007 was for professional charges, the balance being made up out of outlays of various kinds, and bear a relatively small proportion to the sums set down for deputations, engineering, local agents, and miscellaneous expenses, the greater part of which, with the exception of those for deputations, must obviously have been incurred before any tribunal, with the further certainty that if skilled witnesses from London were called in before a local tribunal, the expenses of the proceedings would be seriously increased.

There is almost a general consensus of opinion that two hearings are absolutely necessary. In the first hearing the parties are more or less in doubt as to the case of their opponents, and evidence for which they are not fully prepared, is often placed before the Committee. It is objected that when promoters are defeated at the first hearing they have no appeal; but the Committee are of opinion that this hardship is superficial, for the burden of proof is clearly upon those who come to ask Parliament for special privileges for which they require a Private Act. Moreover, it is open to them in the next session to bring in a new Bill, in which they can meet the objections raised, and which is heard by a fresh Committee. This leads to the remark that promoters, if defeated upon the first occasion, would be much less favourably situated if they brought back their Bills a second time to a permanent tribunal, and that such a tribunal would, by making precedents, gradually acquire fixed habits and preferences, and would not readily adapt itself to the changing views entertained by the public and Parliament. One of the chief difficulties which beset those who recommend the transference of the Committee work now done by the two Houses to an outside tribunal, is the question whether that tribunal is or is not to be required to give reasons for its decisions. If reasons are not to be given, it is difficult to see how Parliament is to exercise any effective control in the absence of individuals familiar with the lines upon which the work has been transacted; if on the other hand, reasons are given, the tribunal will very shortly find itself seriously hampered by precedents of its own creation, which are too nearly akin to the case under discussion to be disregarded, and the disregard of which would not be easy to explain to Parliament, but which might not be so exactly the same as to altogether rule the question at issue.

One witness suggested that reasons should not be given under ordinary circumstances, but only when an appeal was taken to Parliament. It is obvious that the enactment of such a condition would be the surest way of multiplying appeals to Parliament, if only to satisfy promoters or opponents as to the consideration which had guided the tribunal in arriving at its decision.

Nearly akin to this, is the question how it would be likely that a permanent tribunal would deal with new questions of policy which from time to time force themselves on the attention of Parliament. Such questions as that of the payment of interest out of capital during the process of construction of works, and the financial problems of which the set of clauses known as the auction clauses are examples of questions in which difficulty would be almost sure to arise. On this point the whole of Mr. Courtney's answer to Question 4311 is well worthy of serious attention.

There is also a general agreement that Parliament must in every case retain the control of Private Bill Legislation. The majority of the witnesses who object to the present system admit this with perfect frankness. The most common suggestion is that this should be effected by the Bills going through their stages in Parliament as at present, except that at the Committee stage they should be referred to a permanent Commission; and that it should be competent to any member to move either House to order a re-hearing, or to reject the Bill on second or third reading. Against this the Committee would quote Mr. Courtney, who says, "Any scheme which contemplated that Bills should be read a second time and then sent for examination to some outside tribunal, in my opinion, is subject to such objections that they are scarcely worth serious consideration." The Lord Advocate, on the other hand, says, "The re-hearing should not be allowed unless there was a *prima facie* case made out for it by argument in the House itself." It is certain that the strength of the case would be gauged by the number of members who could be got to support the demand for a re-hearing; and the Committee are of opinion that any plan which requires that the attention of Parliament should be called to a Private Bill by motion in the House itself, would bring back all those evils which induced the reference of Private Bills to Select Committees, and would cause an intolerable interference with the time of Parliament. Debates upon Private Bills would almost certainly take place with greater frequency than they do at the present time; and it is not improbable that the time gained by abolishing Committees would be more than lost by debates taking place in the whole House.

Various schemes for the establishment of an outside tribunal have been suggested to the Committee, and whilst recognising their ingenuity, the Committee would point out that they differ essentially from one another, both in the form of the tribunal itself, and more especially in the mode in which the control of Parliament is proposed to be retained.

It appears to the Committee that the remedy of creating a new tribunal far outstretches the evil complained of.

It is not suggested that the more important Railway Bills, or other Bills dealing with engineering works of the first magnitude, could be dealt with better locally than at Westminster. The evidence proves that important companies, even the Scottish and Irish, prefer to transact their business in London. One Scottish witness told the Committee that if an Aberdeen Bill could not be dealt with in Aberdeen, he would prefer that

it should be dealt with in London rather than in Edinburgh. Reference may also be made to the action of the town of Dundee in regard to its arbitration, as to the value of the gas-works when purchased by the Corporation. The witness who appeared on behalf of the Corporation to protest against inquiries on purely local matters being in London was actually Provost of Dundee at the time when that arbitration was held. It might be thought that no subject could be more properly matter for local inquiry than that. While it was in the power of the Corporation to have held that inquiry at Dundee, they voluntarily went to London, in preference to taking the course which they now recommend should be compulsorily imposed upon themselves and all other parties to Private Bills.

The Committee are of opinion that it is by no means certain that any saving of expense would be effected by local inquiries, except in the case of comparatively unimportant Bills, and of Bills which only affect a very narrow locality. By an extension of the Provisional Order system many of these Bills could be inquired into on the spot by an inspector from a Government Department; and in more important cases these Departments might be empowered to conduct an inquiry by a small Commission appointed for the purpose, which would carry greater weight than any single official.

Some relief from the burden imposed upon the time of members of Parliament by the present system of Private Bill Legislation would certainly be obtained by an extension of the Provisional Order system in that class of cases to which it is more especially applicable, such for example as Municipal and Improvement Bills—schemes for short tramways, and undertakings for the supply of gas and water.

The first cost to promoters who proceed under the Provisional Order system is much smaller than by Private Bill. Everybody interested might be heard at the local inquiry without the question of *locus standi* arising, and some advantage in the way of getting rid of opposition is certainly gained by the fact that opponents can see the Draft Provisional Order before it is submitted to Parliament. The total number of Provisional Orders which have been confirmed under the Local Government Board alone between 1874 and 1887 is 1,169; the number refused confirmation is 11; and 11 more were withdrawn by the Board for various reasons. The number of confirmation Bills required was 195.

Except in the case of opposition in Parliament, promoters are put to no trouble or expense in obtaining the confirmation of their Orders. They have not to be present to prove compliance with Standing Orders, and even if there is opposition the promoters have to defend their own Order only at the Committee stages.

The time which members of either house have to devote to Provisional Orders is much smaller in proportion to Private Bills because the oppositions are so few.

Amongst the disadvantages under which the present system of Provisional Orders labours, may be mentioned, that in opposed Orders there may be three inquiries instead of two, as in the case of a Private Bill; and, consequently, the expense to the parties may be increased; and in some cases it is complained that there is not sufficient elasticity in the provisions of those Acts under which Provisional Orders are issued to enable a scheme which might be arranged by Provisional Order to be made complete in all its details.

The Committee are of opinion that though one appeal is necessary, a double appeal in the case of an opposed Provisional Order to both Houses of Parliament is unnecessary; and they suggest that, although there are some objections to frequent recourse being had to a Joint Committee of both Houses, either this course should be adopted in cases in which a local inquiry has been held, or by amendment of the Standing Orders of both Houses of Parliament, no petitioner shall be allowed to be heard a second time.

The Committee believe that almost everything complained of could be remedied by improvements in the present system. They hesitate, therefore, to recommend a new tribunal (of which no one can foretell how it will work) to take the place of Committees of Parliament, which they believe in the main command the confidence of the business world and of the country generally. Many of the witnesses who have demanded the substitution of a permanent tribunal for Committees of Parliament, have frankly stated that they had no experience of railway business, and the Committee are decidedly of opinion that such a change would be unwelcome to those responsible for the conduct of these important undertakings, and little less than disastrous, if, as the Lord Advocate observed in regard to a subsidiary matter, it is expected to be that several years must pass before the new tribunal can settle down to a fixed regime. "The question is what it will be five years hence; in starting any new thing you will have troubles; you cannot put up a building all in a moment."

Considering that there has been no single complaint from anyone familiar with railway matters, the Committee cannot take the responsibility of recommending that these vast interests should be made the subject of a doubtful experiment.

Conclusion.

Upon the whole, and subject to the proviso mentioned in the earlier part of the report, the Committee have come to the conclusion that the main features of the present system of legislation by means of Private Bills and Provisional Orders should be maintained; but at the same time it is capable of amendment and reform. What they would propose in this respect may be briefly summarised as follows:

- (a) The House fees might be reduced by nearly one-half, and yet pay the expenses properly chargeable to them.
- (b) The costs of public bodies, such as corporations, harbour trusts, and public companies, should not only be taxed by the Taxing Officers of the House, but be audited by a public official.
- (c) The length and expense of the notices required by the Standing Orders could be much diminished.
- (d) Possibly some further powers should be given for the awarding of expenses in cases of vexatious or unnecessary oppositions.
- (e) There is room for assimilating and harmonizing the provisions of the Standing Orders of the two Houses; and it would tend to economy and efficiency if questions of non-compliance with the Standing Orders were either remitted to a Joint Committee, or if the decision of the Committee of the House in which the Bill originates were to be held as binding upon the other.
- (f) By judicious alterations in the rules for the reference of Private Bills to the Examiners, it is probable that Committees could begin to sit at least somewhat earlier in the session than is the case at present.
- (g) It would be desirable that more consultation should take place between the officials of the two Houses, so as to secure that too many Committees are not appointed at the same time.
- (h) Some economy of the time of the House of Commons could be effected by originating a still larger number of Bills in the House of Lords.
- (i) It should also be clearly established that the discussion of clauses in the First House should not necessarily be held to disqualify opponents from opposing the preamble in the Second House. If it were not for the fear of this technical objection being taken, a practice which seems to have grown up without any definite authority, it is probable that an even

larger number of opposed Bills would be satisfactorily settled in the First House.

(j) The practice of "starring" Bills sent to Select Committees in the Commons should be extended to the House of Lords.

(k) The system of Provisional Orders might with advantage be extended, and provision made for special local inquiry, in cases of purely local concern, to be held by a stronger tribunal than is the case at the present time.

(l) Provision should be made that opposed Provisional Orders should only be heard before one tribunal in Parliament; that tribunal to be either a Joint Committee or a Committee of one of the two Houses.

(m) It is also worth consideration whether a power should not be given to the Chairman of Committees in either House to report to the House that a matter proposed to be dealt with by Private Bill is rather a matter for local inquiry; and if that report were adopted by the House in which the Bill is arranged to originate, it might be remitted to the Government Department concerned with the class of cases to which it belongs, and, thereafter, the procedure in regard to it might be on the lines of that recommended for Provisional Orders.

GAS CONSUMERS AND THEIR CONTRACTS.

Commenting on the case which recently came before Mr. Biron, Q.C., at the Westminster Police Court, as reported in the *JOURNAL* for Aug. 21 (p. 340), the *Law Journal* says: "An important branch of domestic law in small households is represented by the gas account, although the decision of questions is generally simplified in far too one-sided a way by the power given to companies to cut off the supply. When a person other than the householder has agreed to pay for the gas, the solution of difficulties is not so easy. No pressure can be brought to bear on him by cutting off the gas; and the question is, Who is liable to pay the bill? The question came before Mr. Biron, Q.C., at the Westminster Police Court, and seems to have been decided somewhat too summarily. By section 13 of the Gas-Works Clauses Act, 1847 (10 Vict., cap. 5), the undertakers may, among other things, enter into a contract with any person for supplying with gas any private building; and by section 16 it is provided that if any person supplied with gas by virtue of this or the Special Act neglect to pay the rent due for the same to the undertakers, the undertakers may stop the gas from entering the premises of such person, and recover the rent due from such person summarily if under £20. In the case before Mr. Biron, the house in question had been occupied by Mr. Darbyshire, who had entered into a written agreement to pay for the gas, to be terminated by written notice. Two years ago, Mr. Darbyshire left the premises, and gave verbal notice at the Company's office that the supply should be discontinued. The Company sent a man to disconnect the supply; but as a new tenant was coming in, he refrained, and left the meter. The new tenant paid for the gas he consumed except three quarters' rent, which when he left the house, was unpaid, and for which the previous tenant was sued. The first question was whether the contract between the Company and the old tenant was not rescinded by his notice, accepted by the Company, by their sending a man to cut off the supply, and by taking rent from the new tenant. The Act, it is to be observed, does not require a written contract; so that the contract may be rescinded verbally and by mutual consent. This question appeared to require more consideration; but there was a preliminary question. The summary remedy which the Gaslight and Coke Company were adopting was by the Act applicable only as against 'the persons supplied with gas;' and that this person must be the person actually supplied, and on the premises, seems clear from the fact that only one person is contemplated as liable by the section—that is, the person whose gas may be cut off. This view is confirmed by section 39 of the Act of 1871, which relieves the incoming tenant from liability for the arrears of his predecessor, and by the use of the word 'rent'—that is, payment in respect of occupation."

ELECTRIC LIGHTING OF THE PUBLIC STREETS AT BARNET.—The streets of Barnet were lighted by electricity on Saturday night; and the novelty excited much interest. There are 71 lamps, each placed on a strong ornamental iron post, 12 feet in height, and fitted with a reflector. The dynamo and other machinery are at the Hadley end of High Barnet; and the Company are said to purpose laying down plant sufficient for supplying from 1000 to 5000 lamps for use in private houses and places of worship.

THE PUBLIC LIGHTING OF ERITH.—The people of Erith are already beginning to understand a little of the discomforts which are associated with such a retrogressive system as that of "illuminating" their public streets by means of oil-lamps; and the Chairman of the Local Board has already complained that Messrs. Defries are endeavouring to light the district with rather a short-handed staff. Complaints are made that some of the lamps are not lighted; and in consequence of this the Local Board have called upon Messrs. Defries to pay a fine of 2s. 6d. (to which they are liable under their contract) for each night in respect of each lamp which may not be lighted. Messrs. Defries have pointed out that, as their charge for each lamp is under a 1s. per lamp per week, a fine of 2d. per lamp would be quite sufficient; but finding that the Erith Board are not disposed to look at it in this light (but intend to have their "pound of flesh" for each default), an excuse is now formulated to the effect that the lamps have been properly lighted but have been extinguished by some maliciously disposed persons. This excuse is likely to be unavailing, for the Board consider that if the lamps are not lighted during the time agreed upon, the defect rests with Messrs. Defries.

RICHMOND (SURREY) GAS COMPANY.—The half-yearly meeting of this Company was held last Thursday—Mr. George Noyce in the chair. The report of the Directors announced that, in consequence of the increased efficiency in working, and the general improvement of the works referred to in their last report, they were enabled to make a further reduction of 2d. per 1000 cubic feet in the price of gas. They recommended maximum dividends on all the capital. The Chairman proposed that the report and statement of accounts should be adopted; both being very satisfactory. The capital account, he said, showed a slight increase of expenditure; but they obtained a very good premium for their stock. In the repairs and maintenance account there was a slight increase also, accounted for by the renewal of purifiers. The loss on bad debts was so small that it did not exceed 2s. 4d. per cent. After paying full dividends, the profit and loss account showed a good balance to be carried forward to the next account. In about twelve months the Company had reduced the price of gas to the extent of 8d. per 1000 cubic feet; and were now selling at 2s. 10d.; and as long as they were able to do this, he thought they would be able to hold their own against the electric light. The Company altogether were in an excellent position; and he congratulated the shareholders on the success that had been achieved. Mr. Clarke seconded the proposition, and it was carried unanimously. The Chairman then proposed that dividends in accordance with the report be declared; and this was agreed to. Votes of thanks to the Directors, the Engineer and Manager (Mr. T. May), the Secretary (Mr. E. B. Blott), and the other officers concluded the meeting.

CRYSTAL PALACE DISTRICT GAS COMPANY.

HALF-YEARLY REPORT AND ACCOUNTS.

In the course of their report to be submitted at the half-yearly meeting of shareholders on the 14th inst., the Directors of this Company state that the general working of the concern during the half year to June 30 last has been satisfactory. The price of coal has been less, and that of coke has improved; but owing to the low value of tar, about two-thirds of the total make has been used for fuel. This, it is pointed out, makes the tar sales appear low; but the increased quantity of coke made for sale brings up the total for residual products to £14,247, or £2664 more than in the corresponding period of last year. The increase of private gas-rental over the June half of 1887 is £1623; this being partly accounted for by an augmented consumption of gas, in consequence of the cold and dark weather during the six months. The Directors express regret in having to announce that, owing to continued illness, Mr. H. Palfrey Stephenson declined to be nominated as Chairman. The Directors have, therefore, elected Mr. Frederic Lane Linging to that position; and Mr. Stephenson to that of Deputy-Chairman. The Directors recommend the declaration of a dividend for the half year at the following rates per annum:—6 per cent. on the preference stock; 7 per cent. on the ordinary 7 per cent. stock; 10 per cent. on the ordinary 10 per cent. stock; and 7 per cent. on the new ordinary 7 per cent. shares. This will absorb a sum of £13,625 17s. 4d., less £369 for income-tax. Turning to the accounts, we find that £45,542 was received for gas from private consumers, and £3946 for gas used in the public lamps; making the total gas-rental £49,488. Meter and stove rental amounted to £974; and residual products (as already mentioned) produced £14,247. These various items, with a sum of £57 for "rents," together make the total receipts £64,767. The total expenditure amounted to £48,122, more than half of which (£26,242) was spent in coals, including all expenses. The balance of £16,645 is carried to the profit and loss account; making the net profit to be carried forward to the next accounts (subject to the June half-year's dividends) £21,417. The quantity of coal and cannel carbonized in the half year was 37,697 tons, from which 365,719,000 cubic feet of gas were produced. Of this amount 354,340,400 cubic feet were sold.

DERBY GASLIGHT COMPANY.

The Half-Yearly Meeting of this Company was held last Wednesday—Mr. G. GASCOYNE in the chair.

The notice calling the meeting having been read,

The CHAIRMAN moved the adoption of the balance-sheet. In doing so, he referred to the fact that during the whole of the 70 years the Company had been in existence, their maximum dividend had never yet disappointed them, and had never yet been withheld. Their total receipts for the half year ending June 30 from all sources had been £27,835, and the total expenditure £16,627; the net profit available for dividends being £10,898. The amount of dividends now due and payable was £8659; and the total amount of interest due to the bondholders, £349—thus leaving a surplus of £2239 5s. The surplus in the corresponding period of 1887 had been only £1343. The gains by which the result arose were in nine items—gas and meter rents, £130; residual products taken in the bulk, £404; carbonizing, £203 10s.; fewer bad debts, £94; rates and taxes, £121 19s.; maintenance of works, plant, &c., £96; extra materials sold, £24; maintenance and renewal of mains, &c., £36; and discount on various bills, £59. The total gains amounted to £1269 12s. 7d. The losses were occasioned by the following five items:—Coals, £127 7s.; purifying materials and labour, £94; salaries of the whole of the staff at both establishments, £9 16s.; printing, &c., £91 6s.; and additional meters, £26 16s. The total loss was therefore £267 13s; leaving a balance of "gains" of £902. The quantity of gas manufactured and sold had been diminished by the loss of several mills, which just latterly had unfortunately been shut up. Tar, he might say, had greatly increased, and was still going up in value. Sulphate had risen a little; but coke, he feared, was irredeemable. Referring to the condition of the works, he said that several of the gas-tanks required alteration; and the purifying plant and apparatus was also deficient. Profit had been made on their stock, which fetched £215 on the 10 per cent., and £150 on the 7 per cent.; and this he considered a very satisfactory result. Their good fortune of to-day, however, was not likely always to last to an equal extent; and considering the expenditure they had before them, they must not let their expectations be formed too high. Concluding his remarks, he said the balance-sheet showed that, whilst their gas remained as cheap as any in the United Kingdom, they would be able, after paying substantial dividends and interest on the bonds, to carry over £2249 to the next account; and the reserve fund, compared with what it was in the corresponding period of 1887, had been increased from £14,160 to £18,057.

Mr. RICHARDSON seconded the motion, which was carried.

Dividends were next declared for the half year at the rates of 10 and 7 per cent. per annum.

Votes of thanks were next passed to the Chairman and Directors, and to the Engineers (Messrs. T. and C. Hawksley).

Mr. T. HAWKLEY, responding to the vote, mentioned that he had been Engineer of the Company for about 50 years. He regarded the Company as one of the most secure gas properties in the kingdom. Mr. Goschen's new law relative to the dividends of gas and water companies had certainly conferred a benefit on the Derby Gas Company, whatever else it might have done to other people.

The proceedings then terminated.

EASTBOURNE GAS COMPANY.

The Half-Yearly Meeting of this Company was held on Monday last week—Dr. JEFFERY in the chair.

The notice convening the meeting having been read,

The CHAIRMAN said that it gave him much satisfaction to move the adoption of the report and balance-sheet (see *ante*, p. 341). In the first place, he was satisfied because the Directors had been enabled to offer a good round dividend to the shareholders. They had embarked a considerable amount of money (over £90,000) in what he considered a speculative business, which business, he maintained, should have a high percentage of interest. He was satisfied also because they had been able to make the public participants with them in their success. They proposed to lower the price of gas both to the Corporation and to private consumers. The balance-sheet showed that the affairs of the Company were in a thoroughly healthy state. The balance of revenue was £4556 12s. 8d. They deducted therefrom £18 17s. 6d. for interest; and there remained £4537 15s. 2d., which, added to £2403 18s. 6d. brought forward, gave £6941 13s. 5d. available for dividend. The Directors recommended a dividend at the rate of 12½ per cent. per annum on the £20,000 original capital of the Company, and also upon the £12,490 of "C" shares, and at the rate of 9½ per cent. on the £55,000 paid-up capital of "B" shares. This would absorb a sum of £4517 7s. 6d. and leave a balance of £2424 5s. 11d. to be carried forward. The capital of the Company had been slightly increased since they met last time; but the sale of gas had been a little higher than the rate of interest on the capital. The price of coals was more than 6 per

cent. higher than last year, and this was due to the increased purchase of cannel coal; for the Directors were anxious, not only to lower the price of gas, but to keep the illuminating power at a high standard. They had sold to private consumers 59,373,900 cubic feet of gas, and to the Corporation 8,123,300 feet of gas, at the cost of £11,991 14s. 4d. The leakage had been considerably less than last year. Taken altogether, the residual products showed an increase in price. In regard to the price of gas, he had to propose to the shareholders that it should be lowered 2d. all round—that was to say, that it should be reduced from 3s. 4d. to 3s. 2d. per 1000 cubic feet to the Corporation, and from 3s. 7d. to 3s. 5d. to private consumers. The loss to the Company by this reduction would be something like £1200. The Directors regretted to see that while they had recently given the Corporation of Eastbourne a reduction in the price of gas of 2d., and were now giving them a second reduction of 2d., the Corporation, instead of giving any relief to the long-suffering ratepayer, were putting the money received from the pockets of the Gas Company into those of the Electric Light Company. The latter had been providing lamps on the Parade for £25 each per year; and they now wanted £35. The Corporation, he understood were going to offer them £30 per year. The Gas Company had taken off 2d. per 1000 cubic feet; and the Electric Light Company wanted to put on £10 per lamp. The Chairman then quoted from a circular by Messrs. Long, Wharton, and Down, who, with the Thomson-Houston system of electric lighting, supplied 1200-candle power lamps all night in Taunton and Waterford for £22 per annum. Surely, he observed, if these gentlemen could supply 1200-candle power electric lights all night at a cost of £22 per annum, the Eastbourne Electric Light Company should be able to do it at £25. In conclusion, he referred to the services of the officers—remarking that they were indebted to their Consulting Engineer (Mr. H. E. Jones, M. Inst. C.E.) for much valuable advice; and as to their Manager (Mr. J. Hammond), as far as his connection with him went, he could not speak in too high terms of him.

Mr. T. BENNETT seconded the motion, which was adopted without any discussion.

The retiring Directors and Auditor having been re-elected, It was agreed to increase the Directors' remuneration from £400 to £500 a year.

The usual complimentary votes of thanks having been accorded, the proceedings terminated.

HARTLEPOOL GAS AND WATER COMPANY.

The Annual Meeting of this Company was held last Wednesday—Mr. W. H. FISHER, J.P., in the chair.

The SECRETARY (Mr. T. Trehwitt) read the notice convening the meeting; and it was agreed to take as read the Directors' report for the year ending June 30 last, a summary of which was given in the JOURNAL last week, p. 390.

The CHAIRMAN said he thought he might fairly congratulate the proprietors upon the improved financial position of the Company. Last year they paid a dividend of 5½ per cent.; and to do this, they had to reduce the floating balance by £406. This year they had earned the whole of the dividend that the Directors recommended—that was 3 per cent. more than last year, which on their capital meant £1300. In addition, they were enabled to carry £292 to the surplus balance, which they usually kept in hand. Having alluded to the improvement in business generally in the Company's district, he went on to say that it was an agreeable fact that they had made 192 million cubic feet of gas in the year, or 22 million in excess of last year. As to the cooking-stoves, &c., this department was likewise very satisfactory. Last year they let out 124 stoves; this year 201—being an increase of 77. This increase necessarily required additional accommodation; and it would at once be seen that the time was not far distant when the Directors would have to look forward to extending the ground they now occupied. They were at present bound within the four corners of an Act of Parliament, and nearly the whole of the space comprised therein was covered; and the Board had now under consideration the selection of further space to be submitted for approval when necessity for it arose. As to the water undertaking, this had also been satisfactory; there being an increase in the quantity of water sold of 38 million gallons; and a consequent increase of revenue of £727 odd. The Chairman then made a feeling allusion to the death of Mr. E. Turnbull, who, for the long period of 45 years, had acted as Solicitor to the Company. He concluded his remarks by moving the adoption of the report, and the payment of a dividend at the rate of 6 per cent. per annum, less income-tax.

Mr. BAKEWELL seconded the motion, which was unanimously carried. The CHAIRMAN, replying to a question, stated that the cost of their new sulphate of ammonia works would be roughly £1500.

The retiring Directors were next re-elected; and Mr. Waddington was appointed to succeed Mr. C. Robson, who retired from the Board on account of failing health.

A vote of thanks to the Chairman and Directors concluded the business of the meeting.

WOKING WATER AND GAS COMPANY.

The Ordinary General Meeting of this Company was held last Tuesday, at the Offices, 5 and 6, Great Winchester Street, E.C.—Lieut.-Col. E. GALT, J.P., in the chair.

The SECRETARY (Mr. W. G. Gribbon) having read the notice convening the meeting, it was agreed to take the Directors' report as read. This showed that the total expenditure to date on capital account had been £57,907. The revenue for the half year amounted to £1641; and the expenses on revenue account, including depreciation, to £728 7s. 6d. The Directors have decided to extend their mains to Ripley, at an estimated cost of £800. They state that there is urgent necessity for pure drinking water in that district; a large number of the surface wells from which the inhabitants now obtain their supply having already been condemned. A revenue of £80 to £100, it is said, may be anticipated from the extension.

The CHAIRMAN, in moving the adoption of the report, said the revenue had not shown the elasticity which might have been looked for by some of the shareholders during the past half year. But this was only because by Act of Parliament Guildford had taken over the supply of some of the houses in that neighbourhood, and their own Company had lost a certain sum of money; but in many ways they had gained advantages. The revenue was, however, quite sufficient to pay a dividend of 3½ per cent. on the capital expended, and to carry over a small balance to the next accounts. Referring to the new well at East Horsley, he mentioned that they had sent out adits in two or three directions in order to open the crevices of the chalk and to intercept the water as it poured through. This well was most satisfactory up to the present time; and the Engineer had reported that they were receiving from it alone 50,000 gallons of water daily, which was almost running to waste because it was not wanted. With respect to the purchase of the Act for supplying Farnborough, the North Camp, Frimley, and York Town, the Directors did not feel justified in expending from £10,000 to £20,000 in an enterprise which might not, without more guarantee or some assurance of support, have yielded a

sufficient revenue to pay a dividend. They were now waiting to hear from the Farnham Rural Sanitary Authority whether they were prepared to offer any guarantee to give them 5 per cent. on the outlay of capital. He concluded by moving the adoption of the report, and the declaration of a dividend of 3½ per cent.

Mr. R. HESKETH JONES seconded the motion, which was agreed to. On the motion of Sir H. E. CARTWRIGHT, seconded by Mr. QUILL, a vote of thanks was passed to the Chairman and Directors. The CHAIRMAN having briefly replied, the proceedings terminated.

THE SUPPLY OF OIL GAS AT COLINSBURGH.

It will be in the recollection of our readers that about this time last year some correspondence appeared in the Scotch press (extracts from which were re-published in the JOURNAL) relative to the question of manufacturing gas from oil. The Secretary of the Colinsburgh Gas Company (Mr. C. G. Dawson), who took a prominent part in the controversy, has lately communicated to one of the Edinburgh newspapers the results of a year's working of his Company, as recently submitted to the shareholders. Broadly stated, the results are these: The price of gas, as compared with the coal gas, has been reduced from 7s. 11d. per 1000 cubic feet to 5s.; and instead of the year's operations resulting—as the last year of the manufacture of coal gas did—in a loss, sufficient profit was earned to have paid a dividend of 8 per cent. on the capital of the Company. The Directors, however, only declared a dividend of 5 per cent. These very satisfactory results, he states, have been produced notwithstanding the enormous waste of oil and furnace coal which took place during the first quarter of the year, but which, under better management, has now been checked. Mr. Dawson then gives the statistics (which he says are carefully registered daily) of the working for a recent quarter:—

Gas made and put into holder	Cubic feet.
Gas consumed per meter	112,585
	95,400
	17,185
Deduct for street lamps, free	1,500
	15,685
Leakage	15,685
Or 14 per cent. of the total make.	
Oil made into gas	1,206 galls.
Gas yielded as above	112,585 cub. ft.
Or, per gallon	93½ "
Furnace coal used	12 tons.
Equal to 1 ton for	9,382 cub. ft.

Reverting to last year's correspondence, he remarks that an attempt was made to frighten the consumers by stating that the gas would be more costly; that it was smoky and impure; and that it would quickly choke the pipes with tar, &c. He thinks that the above figures effectually lay the spectre of "condensation;" and those of "impurity," "smokiness," &c., have, he asserts, proved equally groundless. Last year he predicted that the introduction of paraffin gas would prove remunerative to the shareholders and beneficial to the consumers; and he now ventures to say that the prophecy has been amply fulfilled.

Alluding to Mr. Dawson's statement that "the price of gas, as compared with the coal gas, has been reduced from 7s. 11d. to 5s. per 1000," a correspondent writes as follows in last Tuesday's Scotsman, under the *nom de plume* of "Colinsburgh":—"Sometimes the English language is used to conceal our meaning; it is clearly so (inadvertently, of course) in this case. Few, if not all, of your readers can take Mr. Dawson's statement to have any other meaning than this—that formerly in Colinsburgh consumers of coal gas paid 7s. 11d., and that now they only pay 5s. This is not so. It is true we formerly paid 7s. 11d., but last quarter we paid 12s. 6d. for this oil gas; and I am told this sum is arrived at by some wonder-working calculation of Mr. Dawson's, based on the idea that oil gas gives two or three times more light than coal gas, and thus we are called upon to pay 12s. 6d. per 1000 feet. As to its illuminating power, and its being free from smoke, all I know is, that if you use a small burner to save you from its smoke, you are not afforded sufficient light; and if you use a large burner, you must be content to live under blackened ceilings."

Subsequent correspondence has appeared, controverting the statement in the last sentence of "Colinsburgh's" letter. In one communication, signed by "The Manager of the Company," the writer remarks "that any gas would smoke if a burner too large for the pressure were used. At the same time, I assert with confidence that our gas is less smoky than most ordinary coal gas. I had special orders from the Directors to ascertain if there were any complaints in regard to the quality of the gas; and I am glad to say most all the consumers to whom I have spoken now express themselves satisfied with its quality."

Replying to "Colinsburgh's" letter on the 28th ult., Mr. Dawson states that the language he used was "plain and unvarnished." He said in his first letter, that the price of the oil gas "as compared with the coal gas," had been reduced from 7s. 11d. to 5s. per 1000 cubic feet; and further on gives an explanation of his meaning. To quote his own words:—"Having found, by very careful experiment and observation, that the paraffin gas was of such high illuminating power that 100 feet of it was equal in value to about 250 feet of coal gas, my Directors, in order to provide their consumers with an easy and accurate method of comparing the price of their new gas with what they paid for the coal gas they formerly used, and with the coal gas used in the neighbouring towns, charged and now charge the gas as if it were coal gas—converting it in the ratio above mentioned. It matters little, however, how it is charged; the point is, how far the price has been reduced. Now, take 'Colinsburgh's' own method, as he cannot or will not understand ours. By his system we were originally supplying the oil gas at two and a half times 7s. 11d. per 1000 feet, or 19s. 9½d.; now we are able to give it at two and a half times 5s., or 12s. 6d.—reduction in price of oil gas per 1000 feet, 7s. 3½d. The enlarged figures may possibly show the reduction better than the ones I supplied; but for purposes of comparison with coal gas, of course, they are useless, as they show the cost of a gas of over 60-candle power, while ordinary coal gas averages from 20 to 22 candles. For comparison, the figures I gave are accurate and reliable." In regard to smoke from the oil gas, Mr. Dawson says that it is the first time he has heard a complaint since their present Manager was appointed in October last; and he unhesitatingly affirms that the gas is very much freer from smoke and impurity, although it passes through no process of purification, than coal gas, which does. In a postscript to his letter he says: "I understand meters are now being made in Edinburgh to suit a certain kind of oil gas. These register 400 for every 100 feet passing through the meter, which is a much higher ratio than ours, of 250 to 100 feet."

SEVENOAKS WATER COMPANY.—This Company held their half-yearly meeting last Saturday week, when the balance of the profit and loss account submitted (£1133), allowed of the payment of dividends of 8 per cent. per annum on the consolidated stock, and £5 12s. per cent. per annum on the share capital—leaving a balance of £182, which it was agreed should go to form a depreciation fund.

SALFORD CORPORATION GAS SUPPLY.

ANNUAL REPORT OF THE GAS COMMITTEE.

In their report for the year ending March 25 last, the Gas Committee of the Salford Corporation state that the increase in the receipts from the sale of gas has been £1788; and there has also been an increase from the sale of residuals of £2624. These, together with the reductions in the cost of manufacture, distribution, and management, have yielded an additional profit of £5459 10s. 6d. compared with the previous year. There was a saving of nearly £1000 in wages for carbonization, chiefly, it is stated, in consequence of the adoption of stoking machinery at the Regent Road station. Careful attention has been given to maintain the works and plant in a thorough state of efficiency; and an extra expenditure of £500 was consequently incurred for repairs during the year. The provision of £1000 as an estimate for bad debts disappears from the accounts; and the actual amount sustained (£1148 17s. 5d.) is stated. This, however, includes arrears brought forward from previous years. The gross profit of the past year is £61,525 2s. 9d., appropriated as follows:—To interest to depositors and bank interest, £136 2s. 9d.; redemption fund, being principal and interest, £18,233 2s. 5d.; contribution to borough redemption fund, £2089 16s.; annuity to Salford district, £2530; depreciation fund, works and plant, at 3 per cent., £14,575 4s.; depreciation fund, hired meters, at 8 per cent., £3066 6s. The remainder constitutes the divisible profit. It amounts to the sum of £20,894 11s. 7d., which has been apportioned as follows, proportionately to the consumption of gas in each district:—To the Salford district, £11,673 1s. 7d.; Pendleton, £5005 0s. 6d.; Broughton, £4216 9s. 6d. The Committee remark that the new Engineer, Mr. Shoubridge, was appointed on Feb. 20; and they expect under his management that considerable further saving will be effected. They have to some extent anticipated this by reducing the price of gas 3d. per 1000 cubic feet in the borough, and 5d. per 1000 cubic feet in the out-districts.

ROTHERHAM CORPORATION GAS SUPPLY.

REPORT BY MR. THOMAS NEWBIGGING, C.E., ON THE WORKS.

In compliance with instructions received from the Rotherham Corporation, Mr. T. Newbigging, C.E., of Manchester, has recently presented to the members of the Gas Committee a lengthy report on the result of his inspection of the gas-works under their control. In this he states that the works are favourably situated as regards level for supplying the district; but they are in the midst of a considerable population, and owing to their distance from railway and canal, all the raw material of manufacture, and a large proportion of the residual products, have to be carted to and from them. The cost of this haulage, and the nuisance arising from it, are not inconsiderable. The difference in the money value between the site, and one in close proximity to a railway, with a siding connected with the works, he sets down at 2d. per 1000 cubic feet of gas sold, representing £1050 per annum, reckoned on the present gas consumption; and this sum capitalized at 4 per cent., or 25 years' purchase, amounts to £26,250. To remove the manufacturing portion of the works from the existing site to one contiguous to the railway (assuming there is such a site to be found in the district), would entail a sacrifice of two-thirds of the above-named amount of capital. It will be for the Corporation to decide the best course to adopt; but, he adds, there will come a time, when the gas consumption grows, when the Corporation will have no choice but to determine on a new site. In the meantime, it is possible to utilize the existing site so as to double the present gas production upon it, by the erection of a new retort-house in the position occupied by the large coal-shed, and by, at a later period, remodelling the present retort-house and coal-stores. In carrying out the proposed plan, the small 60-feet holder would have to be dispensed with. To put off the erection of the new retort-house, which is absolutely required, will entail an increased cost of working, and jeopardize the gas supply in mid-winter. The whole of the retorts were in action during the last heavy lighting season. He does not approve of the settings of nine retorts, of which the Corporation are just now erecting two double benches; and describes the charging of the two upper retorts, owing to the great height above the floor-line, from an elevated stage moveable along the retort-house floor, as a cumbersome expedient, which will be found costly if extended throughout the length of the building. He considers it is a mistake to expend money in this direction; but does not blame the Manager for suggesting this particular kind of setting under the circumstances, as the exigencies of the demand for gas required that provision should be made for a larger make during the coming winter. The new house should contain a retort-stack 20 feet in width. The present stack is only 18 feet wide; and consequently the production per mouthpiece (under 5000 cubic feet per day) is lower than desirable. With wider benches, and fitted with the best modern appliances, the labour cost and the fuel (coke) account per 1000 cubic feet of gas made and sold would be reduced. To enable the Corporation to use oxide of iron with lime in purifying, it would be necessary to put down two more purifiers, covered by an open shed, and also to erect a shed to cover the space required for revivifying the material, which course he recommends. He also advises manufacturing the ammoniacal liquor into sulphate of ammonia on the works, instead of selling it as at present. In order to obtain the full benefit from the conversion of the liquor into sulphate, the whole of the ammonia should be eliminated from the gas, and secured for sale. According to the Gas Examiner's reports, this is not done at present; the daily tests showing that from 3 to 4 grains of ammonia per 100 cubic feet are present in the purified gas. The fact of so much of this impurity being left in the gas is objectionable, both from the point of view of the loss of revenue, and also by reason of the complaints from consumers to which it gives rise. Mr. Newbigging recommends the erection of a washer-scrubber to remove this impurity. The large underground tank, which is of wrought iron, used for the storage of tar and ammoniacal liquor, he reports as defective, and should be replaced by a new cast-iron tank. New smithy and other workshops, with the necessary machinery and tools, are also required. The distributing mains and services are in good order. The gas-works and the gas department are well managed; and taking into account the disadvantages under which the Corporation labour in various respects, the selling price of gas, he thinks, is reasonably low.

GREENOCK CORPORATION GAS SUPPLY.

REDUCTION IN THE PRICE OF GAS—BALANCE-SHEET FOR 1887-8.

At the Monthly Meeting of the Greenock Police Board held recently, the Corporation gas accounts for the past year and the fixing of the price of gas for 1888-9 were discussed. In the minutes submitted by the Gas Committee, there was given an estimate of the probable revenue and expenditure and profits for the current year, terminating on June 30, 1889. It was estimated that the revenue would amount to £36,800, and the expenditure (including £300 for new meters and main and service pipes) to £25,180. To the latter sum would have to be added £5500 for interest, and £3000 for sinking fund—making the total expenditure £33,680; and leaving a profit of £3120. It was also stated in the minutes that, in view of the estimate of revenue and expenditure submitted to the meeting of the Gas Committee, Mr. Lang, jun., had moved that the Committee recommend that the price of gas be reduced 5d. per 1000 cubic feet (from 3s. 9d. to

3s. 4d.) to consumers by meter, as from May last. To this two amendments were proposed; but the original motion was ultimately carried.

Mr. McONIE moved the adoption of the minutes, with the exception of that portion where it was agreed to recommend a reduction of 5d. in the price of gas, which he said he proposed to challenge by a direct vote of the Board. Referring to the Committee's estimate of the revenue for the year, he said it was about £240 larger than for the year which had closed; but they expected their expenditure would be increased to a slight extent. However, putting all things together, they would find that if trade improved in the town, they would have profits to the amount of £3120, as against £3000 actually made last year. In regard to the proposed reduction, he thought that 2½d. per 1000 cubic feet would be equally just and fair. It would absorb £1600 of the profits which they expected if the price of gas were kept as it had lately stood; but by granting this reduction of 2½d., the profits would be secured. No one would be better pleased than himself if they could reduce the price by 5d. But if they reduced the charge to this extent, the inevitable result would be that the whole of the £3000 which they had in hand would be absorbed; and consequently the Board would not be able to make the two ends meet.

Baillie SHEAVER seconded the motion for the adoption of the minutes, with the exception mentioned by Mr. McOnie.

Mr. LANG then submitted the motion which stood in his name. He said that he had been asked whether he was anxious to press his motion; and his reply was that if he could get an assurance from the Board that the reduction of 2½d. per 1000 cubic feet, proposed by the amendment was an honest intention to sweep away for ever by instalment the unjust system of paying over the profits of the gas undertaking to general police purposes, he would be content with that in the meantime; but he feared that some of the old members were not yet prepared to give up the practice. As they knew, there was a large amount of property on the valuation roll which was valuable for police rates, and in which there was no gas consumed. Then there were manufacturers, shopkeepers, &c., whose consumption of gas was very large in proportion to their rateable rental for police purposes. He, therefore, thought it would be seen that there was an unequal incidence in the matter, as between paying a high price for gas in order that profits might be handed over for the purpose of keeping down police, &c., assessments. The Gas Act provided for the payment of all interest on borrowed money, the expense and maintenance of the works, and the laying aside of a sinking fund; and when all this had been done, it seemed to him that the consumers should get gas at what the outlay represented, and beyond that no profit should be exacted and handed over for the purpose of keeping down taxation in another quarter. When he mentioned that the sum paid over to the Police Board by the gas consumers from 1872 to July 17 this year amounted to £55,600, and in addition thereto, there was, or ought to be, a contingent fund of £4468, and a sinking fund, including the contribution made this year, of £28,012, and redeemed mortgages of £5400, he thought they would agree with him that the gas consumers had been during all that period an over-strained milch-cow, for the benefit of general police purposes, and the payment of a share at least of some most extravagant undertakings on the part of the Board. It appeared to him that it was now high time that the reduction which he had proposed should be granted.

Mr. McINNES said statistics showed that, on the average, after a reduction they recouped themselves every third year. He was quite sure no deficit would arise by taking 5d. off the present price; and he had much pleasure in seconding Mr. Lang's proposal.

A long discussion ensued; and on the voting taking place, fourteen members supported the motion in favour of a reduction of 2½d. per 1000 cubic feet, and the proposal to reduce the price 5d. per 1000 feet had eight supporters; so that the price for the current year will be 3s. 6½d.

The following is the balance-sheet of the Trust for the year to June 30 last. The figures for 1886-7 are also given for the sake of comparison:—

Revenue.			
	1886-7.		1887-8.
Consumers by meter	£24,508 6 10	..	£24,034 19 0

* Including £1800 for the Kilmorie bench.

FATAL ACCIDENT AT THE BECKTON GAS-WORKS.—An inquest was held at the Poplar Town Hall, on Monday last week, by Mr. Wynne E. Baxter, on the body of John Stephens, aged 63, who met with his death at the Beckton Gas-Works on the previous Thursday. From the evidence, it appears that deceased was one of a gang engaged in unloading the steamship *Medway*, which lay alongside the works. As he went to get a drink of oatmeal and water, a huge tank which was hanging from the crane was moved by a man named Manning, and, catching the jib, it became unhooked, and fell down the hatchway on to Stephens, killing him almost instantaneously. A verdict of "Accidental death" was returned.

THE NEW VYRNWY WATER-WORKS OF THE LIVERPOOL CORPORATION.

AWARDS IN RECENT ARBITRATION PROCEEDINGS.

The awards in the arbitration proceedings between the Liverpool Corporation and Mr. T. Hawksley, C.E., and the Trustees of the River Weaver Navigation respectively, in respect to matters connected with the Vyrnwy water scheme, have recently been given.

First, in regard to the dispute between Mr. Hawksley and the Corporation, it will be in the recollection of the readers of the JOURNAL that when the Vyrnwy scheme was first adopted, the work of drawing the plans and carrying out the operations was entrusted to this gentleman. Subsequently a difficulty arose between Mr. Hawksley and the Corporation, which threatened protracted and expensive litigation. It was claimed by the Water Committee that Mr. G. F. Deacon, M. Inst. C.E., the Corporation Water Engineer, had been associated with Mr. Hawksley in the preparation of the plans and the carrying out of the work at Vyrnwy. Mr. Hawksley seems to have taken exception to any divided responsibility in the work between himself and Mr. Deacon; and after the works had progressed to a certain point, Mr. Hawksley objected to a dual responsibility, and practically withdrew from any further control. A difference arose between the Corporation and Mr. Hawksley as to his remuneration. On the one hand, it was stated that Mr. Hawksley was entitled to be paid a sum amounting to nearly £60,000; while on behalf of the Corporation, it was contended that he was really entitled to a far less sum. Mr. Hawksley, to enforce his claim, commenced legal proceedings. The matter was ultimately referred to the Board of Trade, to appoint an Arbitrator to decide between the parties. The Arbitrator selected was Mr. Bosanquet, Q.C.; and this gentleman has delivered his award. From this it appears he has awarded Mr. Hawksley £14,123, in addition to the sums already paid him by the Corporation—amounting to £20,617. He has also decided that the Corporation shall pay the costs of the award, which it is stated will amount to a very large sum—some lawyers estimating it at about £5000. The result of this arbitration will be the addition of a very substantial sum to the already large figure which the Vyrnwy works will cost above the amount originally intended.

The various stages of the arbitration proceedings between the Corporation and the Trustees of the River Weaver Navigation have been briefly reported in the JOURNAL; but we may here reiterate shortly the point at issue. The Trustees contended that the line of pipes should be conducted under the Weaver in a walled passage, culvert, or tunnel, at a sufficient depth in the strata to prevent the possibility of any interference with the navigation or future improvement of the water-way. Mr. Deacon, the Water Engineer, however, was convinced that a less costly and thoroughly trustworthy plan could be adopted without resorting to the construction of a tunnel. The method he proposed was a very simple one. He suggested placing flexible steel pipes at a good depth in the bed of the river, by means of excavating a trench, into which the pipes would fall upon being floated down the river after they had been jointed on the river bank. In his opinion, and in the judgment of eminent Engineers, this plan was far preferable, and not likely to have any prejudicial effect on the navigation, or be a source of danger to vessels using the river. Every effort was made to amicably arrange the matter in dispute, but without avail; and the Board of Trade, under the powers granted to them by the Liverpool Water-Works Act, 1880, appointed Sir Douglas Galton to hear evidence and determine the point at issue between the Engineers of the Trustees and of the Corporation. All the evidence, scientific and otherwise, which could be collected by both sides was presented; and the inquiry was of the most exhaustive character. This, of course, occasioned great expense; but when it is considered that it meant to the Corporation a difference of at least £10,000 in the cost of the works (according to Mr. Deacon's estimate), it is not surprising that their representatives declined to give way. The award of Sir Douglas Galton is in favour of the scheme proposed by Mr. Deacon; so that the cost of crossing the Weaver will be kept at the minimum.

THE PRESENT POSITION OF THE UNDERTAKING.

It is now seven years since a commencement was made with the new works which are destined in the near future to provide the major part of the water required for the supply of the City of Liverpool and the inhabitants within the water supply district of the Corporation; and the report of the Engineer of the works (Mr. G. F. Deacon, M. Inst. C.E.) for the past year, the issue of which is to be looked for within the next few weeks, is expected to announce that with two exceptions—the tunnel under the Mersey and the Norton water-tower—all the more important works, the great masonry dam, the Hirnant, Cynnyon, and Llanfôrda tunnels, the Oswestry filter-beds, the reservoirs at Parc Uchaf, Oswestry, and Malpas, nearly the whole of the aqueducts under railways, together with the intervening pipe-line, are completed. The Cotebrook reservoir, also, is two-thirds finished; and with the completion of the tunnel under the Mersey, Liverpool will have an abundant supply of pure and soft water. The tunnel has just been commenced; and the iron castings with which it is to be lined have been delivered. The achievement of the Vyrnwy scheme is therefore, says the *Liverpool Courier*, simply a question of months; and misconceptions on this point are due simply to a non-acquaintance with the facts.

After a rapid glance at the history of the local water supply from the year 1846-7 downwards, in order to show why the Vyrnwy scheme was entered upon at all, our contemporary proceeds to describe the artificial lake that has been formed by throwing a dam (4½ miles long) across the Upper Vyrnwy Valley. The area of the lake thus created will be 1121 acres; the greatest depth of water, 84 feet; and the area drained, about 22,000 acres, or 39½ square miles. To fill the valley will take, in the estimation of Mr. Deacon, less than an average year of minimum rainfall. "The whole configuration and position of the hills," he says, "is favourable to a high but very variable rainfall; and of the twenty rain-gauges which have been in operation over the drainage area for many years, one to the east of the valley has recorded as little as 49·73 inches in one year, whilst the other to the west has registered 118·51 inches in the same time, or more than three-and-a-half times the average rainfall at Liverpool." During the past year even this average has been considerably exceeded; so that there is no doubt that the estimate is on the right side. The present probabilities are that the lake will be full before next Midsummer, or even by the spring. Indeed, the process of closing the two discharge tunnels through which the compensation water is to flow has already been commenced. Each tunnel, 15 feet in diameter, will be walled up at either end; and a pipe, 30 inches diameter, laid in each. This, however, is slow work, and will not be concluded before October or November. Prior to passing from the lake, the water will have to flow through a huge straining tower built at the entrance to the Hirnant tunnel, and so leave behind all large floating particles. The process of clarification will be completed by the filter-beds at Oswestry; these (four in number) being so constructed that each can be cleaned in turn without interfering with the supply. All this portion of the works has been finished for some time.

A glance at the course of 68½ miles which the aqueduct follows from

Vyrnwy to the existing Prescot reservoir shows that it pursues a zigzag course, up hill and down dale, in what might at first seem a most erratic fashion. The Vyrnwy lake is 830 feet above the mean sea-level; the Prescot reservoir, 277 feet. There is, therefore, at Prescot a pressure of 553 feet of water; and to prevent a great overflow, it was necessary either to mount the reservoir on pillars 553 feet high, or to bring the water down from the lake in stages. Of course the latter method was the only practical one; and it has been carried out by means of relieving reservoirs, each having the same capacity, and built at regular intervals of height up to the level of an imaginary straight line drawn between the respective elevations of Vyrnwy and Prescot. This line is called the "hydraulic gradient." The relieving reservoirs are four in number—Parc Uchaf, in Wales; and Malpas, Cotebrook, and Norton, in Cheshire. Their effect is to make the pipe-line safer, by reducing the static pressure; whilst, because the slope is uniform, the discharge is not reduced in any way. Leaving Vyrnwy, the water passes through the Hirnant tunnel, 2½ miles in length. At the outlet in the valley of the Hirnant, it enters pipes; and for 7 miles flows underground, passing beneath the rivers and streams into the Parc Uchaf reservoir, built at 732 feet above the sea, and capable of containing 2 million gallons. After an undulating course of 4 miles more, the water runs through the Cynnyon and Llanfôrda tunnels, crossing the narrow and precipitous valley of the Morda, which separates them, by a bridge. The outlet of the Llanfôrda tunnel discharges into the Oswestry reservoir; and as the contour of the ground is here favourable to the construction of a large reservoir rising to the "hydraulic gradient" of the aqueduct, advantage has been taken of the fact to give that at Oswestry a capacity of more than 46 million gallons. By this means the remainder of the aqueduct to Liverpool can still be supplied, even though there may be a stoppage in the rugged and somewhat inaccessible mountain district towards Vyrnwy. Besides this, however, there are at Oswestry, in connection with the filter-beds, three clear-water reservoirs with a capacity of something over 12½ million gallons. From Oswestry to Malpas, a distance of 17½ miles, the pipe-line (except when carried on arches across the Wych-brook Valley, Cheshire) is entirely underground. It is almost completely underground also to a hill near the village of Cotebrook, which rises to the level of the gradient, and where there is now nearly completed the third balancing reservoir. At Norton, 11 miles farther on, a little to the south-east of Runcorn, it is necessary, in order to reach the gradient, to build the relieving reservoir on a tower 113 feet high. When built this tower will be one of the finest yet constructed. It will be twice as large as the one in Everton; being 90 feet in diameter, and of the same capacity as the reservoirs already mentioned. It is being proceeded with rapidly; but it is not necessary that it should be completed immediately, for until it be carried out there can be at this point an overflow into the Weaver.

The most difficult part of the entire scheme is the tunnel under the Mersey. At present it is impossible precisely to say when it will be completed. All that can be said is that the Water Engineer fully hopes to deliver water through it during next summer, or at all events next autumn. It is 900 feet long, 10 feet in diameter, and lined with cast iron. On the Cheshire side the water will descend in steel pipes down a shaft slightly larger than the tunnel, and 86 feet deep. On the Lancashire side it will ascend in similar pipes another companion shaft, 104 feet in depth. It will then flow on to Prescot.

The Vyrnwy works are designed to supply ultimately, should the city require it, 40 million gallons a day; but at the present moment they are being carried out only for a supply of one-third of that quantity. If at some future time the needs of Liverpool should demand it, the other two-thirds of the total supply can be obtained by the erection of additional relieving reservoirs, and various other minor works. The erection, again, of another set of reservoirs, and the laying of a further line of pipes, will enable the Corporation to obtain the maximum influx; and all this has been fully provided for.

TOTNES CORPORATION WATER SUPPLY.

INAUGURATION OF A NEW RESERVOIR.

The new reservoir at Bridgetown which has been constructed by the Totnes Town Council, on land leased to them by the Duke of Somerset, was formally inaugurated on Tuesday last by the Mayor (Mr. J. E. L. Lloyd). Among those present on the occasion were several members of the Town Council, the Town Clerk (Mr. E. Windeatt), the Borough Surveyor (Mr. S. Cumming), and the Contractors (Messrs. Brook and Ash). Alderman Kellock, Chairman of the Water Committee, commenced the proceedings by stating that he regarded that day as one which would be chronicled in the history of Totnes; the event being a very important one to the town. The water was supplied from the Bowden Spring, about a mile distant. There had been several ideas with regard to the best place from which the water needed for the reservoir could be derived; and in 1884 several experiments were tried. But it was due to Mr. Martin, of Exeter, who in 1885 recommended the Bowden Spring, that they had their supply from this source; his suggestion being adopted. He looked upon the extra supply of water as most beneficial to the inhabitants. Dr. Blyth, who had tested the water, had reported that it was good in every respect. In conclusion, he remarked that, when foundation-stones were laid, it was customary to present the person performing the ceremony with a silver trowel; but, on the present occasion, he had pleasure in presenting the Mayor with a silver cup, which had been subscribed for by members of the Town Council; and he asked him, in their name, and in that of the town, to accept it as a small memento of the opening of the reservoir. The Mayor, having turned on the water and drunk from the cup, which was handed round to the members of the Council, then formally declared the reservoir opened. Bridgetown, he said, had certainly been short of water in the past. It was gratifying to the town to see the beautiful building sites near them so rapidly taken up and built upon; and nothing was of greater benefit to the community than a plentiful supply of good water. It gave him great pleasure to accept the handsome cup so kindly presented to him. After the ceremony the company were entertained at the Seymour Hotel, by invitation of Mr. Jeffery Michelmores, Steward to the Duke of Somerset.

NORMANTON GAS COMPANY.—In moving the adoption of the Directors' report at the half-yearly meeting of this Company on Saturday, the 25th ult., the Chairman (Mr. Statter, J.P.) stated that they had earned sufficient profit in the past six months to admit of the usual dividend of 8 per cent. being paid. The reserve fund now stood at £1322. The quantity of gas made in the half year was 11,330,000 cubic feet, which was an increase of 401,000 feet over the corresponding period of last year, or about 5 per cent. The leakage was 13½ per cent.; and this was caused by the continual breakage of the mains, owing to the coal-mining operations in the district. The Chairman then went through the accounts in detail; nearly every item, to use his own words, showing "a slow, gradual, and steady progress." The motion was agreed to; and a dividend of 8 per cent., free of income-tax, was declared.

NOTES FROM SCOTLAND. (FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

After a good deal of delay, which may probably be accounted for by the reluctance of the Gas Commissioners of Edinburgh and Leith to show how inadequate an estimate they formed of the Edinburgh and Leith Company's works before the agreement, they have at last issued the reports which they received from Mr. Geo. Livesey, C.E., and Mr. Alfred Lass, F.C.A., respectively on the works and books of the Company. These reports you will probably publish in another column. Both of them are exceedingly favourable to the Company; and if procured in time, might have been made by the Directors the foundation for a higher price.

The abolition of meter-rents may be expected, after the remarks of Mr. Colston in the early period of the negotiations for the transfer of the gas-works, to be one of the leading topics of discussion at the ensuing municipal elections in Edinburgh. There is at present a vacancy in the Leith Town Council; and Mr. Douglas, one of the gentlemen who aspire to occupying the seat, at a public meeting on Tuesday night, put the subject forward. He denounced the present custom of charging a rent of 2s. 6d. a year per meter, no matter whether the consumer received 17s. per week as wages, or had an income of £500 a year. I observe that the Leith Company realized £4796 from meter-rents last year; and as Mr. Lass estimates an annual surplus from their business of £4820, the Commissioners should very soon be able, assuming the larger business of the Edinburgh Company to produce equally favourable results, to strike off the impost.

The inhabitants of Perth were subjected on Thursday night to some temporary inconvenience through an interruption of the gas supply—an occurrence which is so rare anywhere as to make the incident of outstanding interest. During the hours of the largest consumption, the outflow of gas is regulated by a large, and at other times by a small, governor. At eleven p.m., the small governor is brought into use; and on Thursday night, it failed to act. The large governor had been shut off, and the consequence was a stoppage in the gas supply, and the whole of the gas alight in the city, both public and private, went out. The foreman at the works, perceiving what had happened, at once turned on the gas to the large governor—a step which was fraught with more danger than the cutting off of the supply, because the unlighted gas then began to flow out of the open burners. Fortunately, no accident happened. In the streets the gas escaping from the public lamps smelt very strongly; and the hour being late, it was some time before the lamplighters could be assembled and started to re-light the lamps.

The oft-vexed question of the interference with public thoroughfares by gas companies, was raised at the meeting of the Haddington Town Council on Monday. The Town Clerk, it was stated, wrote to the Gas Company informing them that Sidegate Street was to be re-caused, and suggesting that the Company would have a good opportunity of examining their pipes. No notice was taken of this letter; but after the new causeway had been laid, the Company proceeded to open up the thoroughfare. It transpired that the town made no charge on the Company for damage done to the streets; and that nothing further than grumbling could be indulged in.

Though the Committee who are investigating the allegations of over-charges for gas in Aberdeen have not yet issued their report, it is announced that they have discovered the increases to have been generally of very small amount, and that, in a good many of the cases put before them, there had been a decrease in the amount charged.

At a meeting of the Elgin Gas Commissioners on Monday, it was intimated that the valuation of the gas-works and plant had been raised by the Assessor from £1043 to £1322; and a Committee was instructed to look into the matter. An offer was accepted for the surplus tar and liquor produced at the works during the ensuing year, at the rate of 2s. 6d. per 100 gallons.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

The annual meeting of the Partick, Hillhead, and Maryhill Gas Company was held yesterday. Mr. Henry Cowan, the Chairman of the Company, presided. The report of the Directors for the year ending June 30, a summary of which was given in the JOURNAL last week, was taken as read. The Chairman, in moving the adoption of the report, referred to the death of the late Secretary, Mr. J. C. Maccall, C.A., and to the appointment of his successor, Mr. J. Graham, C.A. In regard to the business of the Company, he was pleased to state that it exhibited a marked improvement. The make of gas for the year showed an increase of about 12 per cent.; and for the two months of the current year there had been a considerable increase in the make over that of the corresponding period of the preceding year. He trusted this would continue; and as there had been a great amount of building going on in the district, he had no doubt that it would bring into play much of the Company's distributing plant. The net balance at the credit of profit and loss account was, he remarked, £7445, of which the Directors proposed to apply £1942 in extinguishing the balance at the debit of the suspense account; and in accordance with the decision of the four Judges of the First Division of the Court of Session, they recommended that payment be made to the preference shareholders of a dividend for three years, less income-tax—thus absorbing £4950, and carrying forward a balance of £552 10s. 9d. to the present year's account. Notwithstanding the reduction in the price of gas from 3s. to 2s. 10d. per 1000 cubic feet, the revenue account showed an increase of about £3000 profit over that of the preceding year; and as the coal contracts had been made on very favourable terms, and additional prices had been obtained for the residual products, they hoped that the present year would show as favourable results. After referring to the efficient state in which their Manager (Mr. Levi Monk) was maintaining the works, he alluded to the debenture debt, which now stood at £50,500; showing a reduction of £10,310 in two years. With this reduced capital they were doing a much larger amount of business. He thought it proper to state that negotiations were at present pending with the Glasgow Corporation Gas Trust for the purchase of the works, in the event of the district in which they were situated being annexed to the city; and as soon as these were completed, a meeting of the shareholders would be called to consider the terms submitted. He concluded by moving the adoption of the report. The motion was seconded by Mr. J. King, and unanimously agreed to. It was subsequently resolved to vote a sum of 200 guineas to the Directors for their services during the past year; being an increase of 50 guineas.

A considerable amount of talk has taken place in the western and north-western suburbs of Glasgow within the past few days regarding the negotiations referred to in the previous "Note." Amongst "outsiders," it is generally understood that the negotiations originated with the Glasgow Corporation Gas Committee; and it is stated that the sum which it is proposed to offer for the works is £172,000, or £2000 more than I mentioned last week. It is evident that the Gas Committee mean business; but on the part of the Directors of the Company, there does not seem to be any

very marked desire to sell their property to the Corporation, more especially as the works have been put into a very healthy condition, and the demand for gas has greatly increased throughout Maryhill and the adjoining suburbs. Persons who have more or less interest in the proposed purchase are throwing out "feelers" in various directions as to the valuation which practical men put upon the works, and as to the abilities of the Manager, Mr. Levi Monk. On the point last mentioned there is not room for the shadow of a doubt, when the present position of the Company and of the works is compared with that a couple of years ago. In the event of the works being acquired by the Glasgow Corporation, there seems to be every probability that Mr. Monk will be asked to transfer his services to the new proprietors. In connection with this matter, it is worthy of mention that the shares of the Company have of late been dealt in almost daily on the Glasgow Stock Exchange. Last Saturday the ordinary shares changed hands at 90s. per share. On Monday the price was slightly advanced; and holders at the close wanted 91s. The preference shares were sold on Thursday at £6 10s. per share; and the ordinary shares were quoted at the close at 90s. Yesterday 89s. per share was paid, which was the sellers' quotation at the close.

At the meeting of the Kilsyth Police Commissioners on Monday, it was agreed that the price of gas should be reduced from 4s. 7d. to 4s. 2d. per 1000 cubic feet, the reduction to date from May 15 last. It was further resolved to supply the consumers with Bray's burners free of charge; and that those consumers who required Bray's "Special" burners should be supplied with them at 1d. each.

At a meeting of the Directors of the Biggar Gas Company yesterday week, it was resolved to reduce the price of gas 5d. per 1000 cubic feet as from May 26 last.

A parcel of 39 £5 shares in the Ayr Gas Company have recently been sold by auction at £5 12s. each; and on the same occasion 67 £2 shares in the Newton-on-Ayr Gas Company realized £2 17s. to £3 per share.

The Glasgow pig-iron warrant market has been buoyant all the week, with a large amount of business done from day to day. Prices have advanced during the week from 3d. to 4d. per ton; the finish yesterday at noon being about the best prices. A number of inquiries from America and the Continent have been reported during the week; and during next week a large quantity of special iron will be taken from store for shipment. Some of the special brands of makers' iron have been advanced in price during the past week or so, to the extent of 1s. to 2s. per ton.

The local trade continues to show an improvement. In some of the western districts, shipments are still in excess of the production, which has been curtailed by the policy of the miners taking an idle day at the end of the week. Slight advances are now being conceded for furnace coal, and at the Glasgow Terminus, main coal is quoted at 5s. 9d. to 6s. per ton; ell and splint coal also being firmer in price.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Sept. 1.

Sulphate of Ammonia.—The healthier tone apparent about a week ago has gradually changed to a very depressed feeling, due in great measure to the rapid reduction of the London quotations. This movement has created some surprise among country makers. The small quantities produced at the present time seemed hardly to call for a lowering of prices; nor are the cheaper rates likely to increase the immediate demand. Buyers generally now anticipate doing better during this month. The facts, as far as the country is concerned, are these: Very little offering, and immediate parcels scarce at nearly all the ports; hence consumers may be mistaken in reckoning upon very low prices in September, when the demand, although later (corresponding with the lateness of the season) may nevertheless set in sharply. To-day's market, however, closes very weak, with sellers at £11 7s. 6d., Hull and Leith.

LONDON, Sept. 1.

Tar Products.—There is more enquiry for benzole, and 90 per cent. has advanced 3d. to 4d. per gallon. Creosote is also scarce; and higher prices are asked for oil free from salts. But the market generally is slack; and both buyers and sellers are somewhat indifferent. The following prices represent the week's quotations:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzole, 90 per cent., 3s. 1½d. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—Sulphate of ammonia is not only neglected, but buyers cannot be found, even with an inducement of 2s. 3d. per ton lower price. There can be no doubt that the market is in the hands of "bear" operators; and manufacturers would do well to withhold from selling in the meantime. Prices: Sulphate of ammonia, £11 to £11 5s. per ton, less discount. Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the Chemical Trade Journal, Sept. 1.]

Sulphate of Ammonia.—Values have improved all round; and to-day's price at Hull may be taken as £11 10s. per ton. At Liverpool prices are £11 10s. to £11 12s. 6d. per ton; and Beckton £11 5s. per ton. The market prospects are altogether brighter; and there is every reason to look for better prices than those which have been ruling latterly. Nitrate of soda, however, still offers freely at low rates; and this competitor must be borne in mind by those who may desire to force values of sulphate beyond a safe point.

Tar Products.—The position of the market for benzoles is without change; and prices remain at 2s. 4d. and 2s. 1½d. for 50's and 90's respectively, with very little business doing. Crude carbolic is decidedly weaker, at 3s. 1½d. per gallon for 60's at makers' works. Even lower offers have been refused by some buyers. Anthracene still commands good prices, both for "A" and "B" qualities. Pitch is without change. The demand for creosote continues; and makers realize for good qualities 1½d. per gallon at works, and 3d. per gallon in casks at ports of shipment.

The Rochdale Gas Committee have resolved to recommend the Council to increase the salary of Mr. Stenhouse, the Chemist at the gas-works, by £40 per annum. Mr. Stenhouse has filled his present position for six years. The Water Works Committee propose also to advance the salary of Mr. Tomlinson, the Manager of the water-works, by £50 per annum.

At the first ordinary meeting of Bell's Asbestos Company, Limited, last Wednesday week, the Chairman (Mr. J. Bell) announced that the profit exceeded £10,000, and the Directors thought they might prudently pay an interim dividend of 7s. 6d. per share, which would absorb £7500. He said they looked forward to rendering a satisfactory statement at the end of the year. The Company were trading vigorously and prosperously.

ST. MARY CRAY GAS COMPANY.—The report presented at the half-yearly meeting of this Company showed that the amount available for division was £1952; and from this it was unanimously resolved to pay dividends at the rate of 10 per cent. per annum on the original shares and 7 per cent. upon the additional capital.

EAST WARWICKSHIRE WATER-WORKS COMPANY.—The second half-yearly meeting of this Company was held last Saturday week. From the Directors' report, it appeared that during the past six months the supply of water had been nearly doubled; over 300 houses being now connected with the Company's mains. The Chairman stated that up to the present time more than nine miles of pipes were actually laid; and contracts had been entered into for upwards of 1000 yards more, so that in a very short time they would have laid over ten miles of pipes. The greater portion of Nuneaton was now covered by mains. The present yield of their well was 121,248 gallons per 24 hours. The report was unanimously adopted.

MAIDSTONE WATER-WORKS COMPANY.—The report presented by the Chairman (Mr. C. Ellis) at the half-yearly meeting of the shareholders of this Company on the 23rd ult., was not such a favourable one as those submitted in the two previous half years. This he attributed to the large number of houses now unoccupied in Maidstone, and the considerable decrease in building operations. The accounts showed that the water-rents amounted in the half year to £3545 3s. 2d.; and that there was a profit of £1486 19s. 6d. available for dividend—making a sum of £4613 at the credit of the profit and loss account. From this the Directors recommended the payment of a dividend of 3½ per cent. for the half year on the 10 per cent. shares, and 2 per cent. on the 7 per cent. shares. After some discussion, the report was adopted, and the dividends recommended declared.

ACCRINGTON GAS AND WATER COMPANY.—At the half-yearly meeting of this Company, held on Monday last week, the balance-sheet submitted for adoption, showed that the expenditure on capital account during the six months to June was £2232, of which £1434 was spent in the enlargement of the No. 1 reservoir at Mitchell's House, £621 for new main pipes, and the remainder for new service pipes and meters. There had been a decided increase in the revenue from both gas and water; and the balance consequently available for dividend was £8966. Out of this sum the Directors recommended the usual dividend of 10 per cent. per annum on the "A" stock of £10,500; and 8 per cent. per annum on the "B" stock and called-up shares—carrying forward the balance to the current account. The number of additional consumers during the half year was: Gas, 99; water, 272—total, 371.

BARNSTAPLE WATER COMPANY.—At the half-yearly meeting of the Barnstaple Water Company on Monday last week, it was reported by the Directors that the works were in a most satisfactory condition. During the last session of Parliament, the Royal Assent was given to the Company's Bill, which enabled them to raise additional capital and to construct new works. The Engineer (Mr. T. Hawksley, C.E.) had sent out specifications, and tenders were being solicited for carrying out the work. As soon as the Directors were furnished with an estimate of the cost, they would at once issue new shares to the public. The Chairman (Mr. E. Dennis), referring to the proposed new works, said that they had already entered into a contract for the supply of the pipes required. As soon as possible, the new shares would be put up to public auction. They would be £10 shares, and would be limited to 7 per cent. dividend. The Directors' report was adopted; and a dividend of 10s. per share was declared.

PORTSEA ISLAND GASLIGHT COMPANY.—At the half-yearly meeting of this Company, the report for the six months ending June 30, which the Chairman (Mr. T. S. Edgcombe), submitted, disclosed a very satisfactory state of affairs. The revenue for the half year amounted to £42,665 16s.; and the expenditure allowed a sum of £12,724 1s. to be carried to the profit and loss account. The Directors recommended the payment of dividends at the rate of 12½ per cent. per annum on the "A" and "B" shares, 11½ per cent. per annum on the "C" shares, and 5 per cent. per annum on the Company's stock, payable (less income-tax) on Sept. 1. The concluding recommendation in the report, "that the usual donation of coke to the value of £60 be distributed among the poor of the borough during the ensuing winter," is one that might receive consideration at the hands of the directors of other companies who have any surplus coke for disposal. The report was adopted, and the various recommendations were agreed to.

CREDITON WATER SUPPLY.—A special meeting of the Crediton Improvement Commissioners was held yesterday week, to consider a communication from the Local Government Board relative to the water supply. The letter stated that the Board had received a communication from the executors of Mr. S. Price, who work a tannery at Bow, saying that if the proposed scheme for obtaining water at Walson was carried out, it would have the effect of withdrawing the supply they had enjoyed from time immemorial. If it interfered with the water, they would be compelled to sue in the Courts for redress; if, on the other hand, it was abstracted through percolation, they would protect themselves by sinking a rival shaft. They, therefore, prayed the Board not to sanction the project; but to request the Commissioners to give further attention to the other schemes which had been brought forward. It was unanimously resolved that the Clerk should write, stating that the Commissioners had given the matter full consideration, and they hoped that the Local Government Board would grant the loan of £10,000, as desired, in order that the work might be carried out without further procrastination. The letter further stated that parties were protected from damage by section 308 of the Public Health Act, 1875.

REDUCTIONS IN PRICE.—The Directors of the *Sevenoaks Gas Company* announce a reduction in the price of gas throughout the whole of their area of supply of 2d. per 1000 cubic feet.—The *Airedale Gas Company* have decided to allow an additional discount of 1d. per 1000 cubic feet on all accounts paid within the usual time after they fall due.—The Directors of the *Isle of Thanet Gas Company* have reduced the price of gas to private consumers from 3s. 3d. to 3s. 1d. per 1000 cubic feet.—The *Kidderminster Gas Company* have notified to the Town Council a reduction in the charge for lighting the public lamps; the charge for "summer" lamps to be in future 13s. 6d., and for "winter" lamps 44s. 6d. per lamp.—It is reported that the Directors of the *Gloucester Gas Company* have decided to reduce the price of gas 2d. per 1000 cubic feet.—It has been intimated to the consumers of gas in the district of the *Barnet Gas and Water Company* that, on and after the 5th of January next, there will be a reduction of price to the extent of 3d. per 1000 cubic feet.—The *Farnworth and Kersley Gas Company* have reduced their price by 2d. per 1000 cubic feet; the charges in future to be: To consumers, when the quarterly consumption is under 150,000 cubic feet, 3s. 4d. per 1000 net; between 150,000 and 400,000 feet, 3s. 1d. net; 400,000 feet and upwards, 2s. 10d. net. The price charged to the Local Boards of Farnworth and Kersley for gas supplied to the street lamps will also be reduced to 2s. 8d. per 1000 feet net.—The Directors of the *Milnrow Gas Company* have decided to reduce the price of gas 3d. per 1000 cubic feet; the reduction to take effect from June 30. The price will now be 3s. 9d. per 1000 feet, subject to discount.

INCREASE IN THE PRICE OF COAL IN LANCASHIRE.—The coalowners of West Lancashire have resolved to advance the price of house coal, as from the 1st inst., by 1s. per ton; steam coal (other than slack), 6d. per ton; and slack, 3d. per ton. A similar advance is also to be made in the South East Lancashire district; but as regards engine fuel it is to date from the 1st of October.

NEGLECT TO PROVIDE CONSTANT SERVICE WATER-FITTINGS.—At the Greenwich Police Court last Thursday, a fine of £5, with £2 2s. costs, was imposed on the owner of several houses in Deptford Lower Road, for neglecting to comply with the usual statutory notices to provide proper fittings in order to render such houses suitable for receiving a constant supply of water. The matter had several times been before the Court, and adjourned so as to give defendant an opportunity of complying with the requirements of the Southwark and Vauxhall Company.

PORTISHEAD DISTRICT WATER COMPANY.—During the half year ending June 30 last, the income of this Company from domestic services was slightly in excess of that for the corresponding period of last year; and the Directors anticipate some further improvement in the current half year, owing to the recent activity of the trade in the Portishead Docks. During the past half year the Directors accepted a tender for the construction of a storage reservoir at Carter's Springs, which, they now report, is nearly completed. It is believed that the reservoir will prove of considerable advantage to the Company in the future.

FALMOUTH GASLIGHT COMPANY.—In their annual report, the Directors of this Company state that during the past year some unexpected and heavy repairs had been carried out, chiefly to the new purifiers; and these, together with the additional cost of coal, had considerably added to the expenses. The Assessment Committee raised the rating of the gas-works £200; but the Directors appealed against any addition being made. After considerable negotiations, it was agreed to settle the matter by arbitration; Mr. Morgan Howard, the County Court Judge, being appointed arbitrator. His Honour has heard the case, but has not yet given his decision. Reference is made to the appointment as Manager, in August last, of Mr. J. W. Buckley, formerly of the Southport Corporation Gas-Works, and to the retirement of Mr. F. M. Harris. Although the profit was not as large as in some former years, the Directors paid the usual interim dividend of 5 per cent. in February last; and they now recommend the payment of 5 per cent. for the second half of the year, together with a bonus of 6d. per share, to pay which they had had to draw from the suspense account.

NORTHERN COAL TRADE.—The movement in the coal trade of the north still continues; and there is a decided improvement in the demand for gas and manufacturing coal. Steam coal continues fairly active; best qualities being sold at about 7s. 6d., whilst the demand shows as yet no sign of falling off. In gas coal, the event of the week has been the tendering for the supplies of the Newcastle and Gateshead Gas Company. As yet the result has not been declared; but it is believed that the bulk of the tenders are at an advance on the prices of the past year, of from 3d. to 4½d. per ton. Still, the prices are low; for most of the coal offered is comparatively near to the works, and thus the cost of carriage is limited. It is expected that the contract will be allotted at about 6s. to 6s. 1½d. per ton delivered; so that it will be seen that the coal is obtained at a low price, owing to the favourable situation of the works. Manufacturing coal is also dearer this week; and there is a disposition to contract ahead for coal of this class for some time, and that at prices from 3d. to 6d. per ton above the rates which are now current. Household coal is still depressed; the demand being limited.

CANTERBURY GAS AND WATER COMPANY.—In moving the adoption of the report of the Directors of this Company (which was noticed in the last number of the JOURNAL), at the half-yearly meeting of the shareholders yesterday week, Colonel Horsley, who presided in the absence of the Chairman, said he considered the statement was in every way satisfactory. The estimate they formed when they made a reduction in the price of gas to 2s. 10d. was found to be correct; and they had continued to pay their usual dividend. The large gasholder which had been erected from the plans of Mr. H. E. Jones, M. Inst. C.E., had been fully tested, and was now in working order. It had cost £8499 18s. 5d.; and they were told it was one of the cheapest holders that had been built. It had cost £13 per 1000 cubic feet; whereas the usual charge, he believed, was about £18. As regards the water-works, no capital expenditure had been required during the half year. All was in good order, and working well. The balance on the profit and loss account to be carried forward, subject to the half-yearly dividends, was £5908 11s. 2d. The report was approved; and a dividend at the rate of 8 per cent. was agreed to.

SUNDERLAND GAS COMPANY.—The revival in trade, which has to some extent prevailed during the last twelve months, has had (we learn from the Directors' annual report) a favourable effect upon the revenue of this Company; the gross receipts for gas and residuals showing an increase of £2947 for the year ending June 30 last, while the make of gas exceeds that of last year by 5·61 per cent. The Directors, in anticipation of still further demands upon them, have entered into contracts for the erection of four new purifiers at Hendon, which, with other necessary extensions, will be completed in time to meet the requirements of the coming winter. The revenue account shows that £41,920 11s. 5d. was received for gas and meter rentals; £11,383 18s. 2d. for residuals; and £169 19s. 8d. under the head of "sundries"—making a total of £53,474 9s. 3d. Adding to this the sum of £8929 brought forward, gives a total to the credit of the revenue account of £62,403 9s. 11d. On the other side, the total expenditure amounts to £41,019 5s. 9d., which leaves a divisible balance of £24,384 4s. 2d. An interim dividend was paid in March last; and the Directors now recommend the declaration of a like dividend—5 per cent. on the original stock, and 4½ per cent. on the additional capital stock of the Company.

THE LIGHTING OF THE ABERDEEN MUSIC-HALL.—Messrs. J. Milne and Son, of Edinburgh, having been requested to report as to the adaptability of the Wenham lamp for the lighting of the Aberdeen Music-Hall, have submitted a plan substituting three groups of these lamps for the three sun-burners at present in use. One group of seven Wenham lamps was fixed in position, and tested on Monday last week. Each lamp is supplied with flash-light tubes; and the lamps are simultaneously lit by turning on a single tap in the gallery. The difficulty hitherto experienced, of providing a ready means of manipulating the lamps in such a lofty interior, has in this case been successfully overcome; an ingenious apparatus having been devised by Messrs. Milne, by which the whole group can be easily lifted for cleaning or repairing purposes. The seven lamps tested on Monday are of the largest size—No. 4—and each consume 15 cubic feet of gas per hour—rather more than 100 feet in all. The sunlight superseded contained 297 burners, and consumed fully 400 cubic feet of gas per hour; so that the saving involved by the adoption of the Wenham system is thus about 75 per cent. Much satisfaction was expressed with the light afforded; and it is probable other sun-burners will be replaced with these lamps.

MANCHESTER CORPORATION WATER-WORKS ACCOUNTS.—For the year ending March 31 last, the Water-Works Department of the Manchester Corporation shows a surplus income (after providing for the necessary payment to the sinking fund) of £4378, from which has to be deducted the adverse balance brought forward, of £1393; leaving an amount to the credit of the revenue account at date, of £2984.

LEWES WATER COMPANY.—The receipts of this Company for the year ending June 24 last amounted to £3935 8s. 10l., and the expenditure to £1083 16s. 6d. The balance allowed of dividends being paid of 10 per cent. upon the original share capital, and of 7 per cent. upon the new share capital, and also a bonus of £1 5s. on the original shares, in part payment of the arrears due to the holders thereof. At the annual meeting of the shareholders on Wednesday, general satisfaction was expressed at the growing prosperity of the Company.

THE NORWICH TOWN COUNCIL AND ELECTRIC LIGHTING.—At the quarterly meeting of the Norwich Town Council last Tuesday a resolution was passed—"That a Committee be formed to be called the Lighting Committee, and that it should forthwith inquire into the cost and method of Electric Lighting in Brighton, Taunton, Eastbourne, Poole, Bradford, and any other towns in which electric lighting is in use, and report to the Council at its next meeting." The mover of the resolution said his object in bringing the question before the Council was that they might be posted up with the fullest information as to the improvements and progress of electric lighting. Since they tried an experiment with the electric light in Norwich, he believed great improvements had been made in this method of lighting; and the Council ought, he considered, to have ample information on the subject.

THE BOROUGH AUDITORS AND THE MANCHESTER CORPORATION GAS DEPARTMENT.—The report of the Auditors (Messrs. Lees and Graham, Chartered Accountants), on the accounts of the Manchester Corporation for the year ending March 31, will be submitted to the Council at their meeting to-morrow (Wednesday). The report contains the following paragraph in regard to the gas-works property of the Corporation:—"The Gas Department, after providing for sinking fund and contributing to the city fund the sum of £22,331, shows a surplus on the year's working of £17,925 13s.; which, deducted from the adverse balance on revenue account of previous years, leaves the present deficiency at £27,931 14s. 3d. During the year we have called the attention of the Committee to the question of depreciation, which is charged against the income of this department, in addition to the amount set aside for sinking fund; and we have represented that this is unnecessary, seeing that the sinking fund ultimately provides for the entire cost of works out of revenue. In effect, the revenue account is charged with depreciation twice over; and the city fund deprived of an amount which it would otherwise be entitled to receive as a contribution towards the rates. We understand the Committee have this subject under their serious consideration. The profits of the department, which were formerly handed over to the Improvement Committee, are now placed to the general credit of the city fund."

WEST SURREY WATER COMPANY.—The half-yearly meeting of this Company was held last Tuesday. From the report and statement of accounts we see that the income for the half year, after making provision for empty houses, irrecoverable rates, &c., amounted to £2137, and the expenditure to £873. Compared with the corresponding half of last year, the income exhibits an increase of £157 17s. There were laid 3031 yards of 3-inch and 4-inch mains; and 65 new supplies were connected, representing a future rental of rather more than £196 per annum. The new filter-bed, which is in course of construction, will shortly be completed. Referring to the Bill which the Company promoted in the last session of Parliament, the Directors report that it received the Royal Assent on July 24. It will be remembered that the object of the Bill was to increase the share capital by £40,000 and the borrowing powers by £10,000. It is intended to issue £12,500 of debenture stock as soon as practicable, in place of the £12,500 of mortgage bonds outstanding, £9125 of which fall due in January next. As it may be necessary soon to acquire land, under the powers of the new Act, for the construction of a subsiding reservoir, it is proposed to issue further ordinary or preference share capital, as the capital authorized under the Company's Acts of 1869 and 1877 has now all been issued and paid up. The report and accounts were adopted; and the payment of a dividend at the rate of 3 per cent. per annum upon the ordinary shares was agreed to.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—**GWYNNE & CO.,** ADDRESS FOR TELEGRAMS: "GWYNNEGRAM LONDON."
HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.
TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, SEPTEMBER 11, 1888.

SIR FREDERICK BRAMWELL'S PRESIDENTIAL ADDRESS. THE British Association for the Advancement of Science met last week at Bath; and Sir Frederick Bramwell, the President for the year, delivered an inaugural address which has by this time gone the round of the press, and evoked hundreds of commentaries. Most of these newspaper critics are attracted by the peculiar description with which Sir Frederick Bramwell prefaced his address. He said that his remarks

would be divided into two sections, the first of which would be devoted to the "next-to-nothing;" while the second would be a eulogium of civil engineers and their works. Sir Frederick Bramwell, eminent as he undoubtedly is, has his detractors; and there are many who do not believe in him. To these irreverent ones the thought will occur that this is not the first time that the great Engineer, who is in such demand as an expert witness in patent-law cases, has made good use of next-to-nothing. The address as a whole has not made a deep impression on the public; being generally regarded as heavy, and lacking novelty. The scheme of it is good; but the execution is certainly disappointing. There are two extremes into which Presidents of the British Association are apt to fall. Some of them set the semi-popular character of their audience entirely at naught, and discourse hour after hour upon the most abstruse refinements of their own speciality; while others think chiefly of this and of the still shallower newspaper readers who will peruse the reports of their address, and shun everything but trivialities which they think will be understood by the veriest skimmer of news who at any time would prefer a murder to a monologue. There is plenty of scope for a really interesting and instructive address between these extremes; but it requires a man of real genius for exposition to make the best use of the opportunity. The President of the British Association occupies an exceptional position. He is regarded by his countrymen as the spokesman of contemporary science. What the public want to hear from his lips is an intelligible account of the work of scientific men—an exhibition of the fruit of the laboratories—for the year. They do not expect him to know everything; but as a specialist with scientific sympathies not wholly restricted to his own department, they look to be guided by him over his own scientific domain, and to enjoy the view therefrom over the surrounding country. If one judges Sir Frederick Bramwell's address upon this principle, it will be found decidedly disappointing. It did not even fulfil the author's own description; for the exposition of the value of apparently small facts which was promised by the fantastic sub-title already mentioned, is by no means so striking as it might have been in any part of the composition. The only point in which it comes up to the author's promise is in respect of the laudation of the civil engineer as a servant of humanity and a hastener of human progress in the way of material civilization. It does this with all unction; but somehow the subject lacks novelty and interest. Civil engineering is a noble study, which has for its objects not merely the direction of the great sources of power in Nature for the use and convenience of man, as Thomas Tredgold defines it, but also the correction, for man's convenience, of the conditions under which he exists upon this planet. It is the province of civil engineering to smooth man's way upon the earth and over the sea; to facilitate his communications with his kind, and so to improve the distribution of goods and ideas among the nations; and to enable man to escape in many respects from the tyranny of natural influences. All this is patent; and engineers are not at all likely to fall short of a due appreciation of their own worth. To the student of humanity at large, however, many of the triumphs of engineering sometimes appear of only questionable value in the great valuation of human blessings and burdens. Sir Frederick Bramwell talks of a steam-engine as though it were an unmixed good; but a philanthropist does not regard the factory system of manufacture, which is the direct outcome of steam-power machinery, as an undoubted blessing of civilization. It is doubtless a great thing for an engineer to make a machine of iron and brass to do the work of men's hands; but when the converse happens as a consequence of his triumph, and generations of men are reduced to work as mere machines, the result is not so pleasant to contemplate.

General considerations of this order are not for us, however; and we must turn to the portions of the address that treat of subjects in which we are specially interested. Of course, Sir Frederick Bramwell had a good deal to say about steam-engines; but he said nothing new. Referring to the wastefulness of steam-engines, even of the best construction, he followed the late Sir William Siemens in holding out great expectations respecting the gas-engine as a substitute for the steam motor. He gave a brief history of the gas-engine, from the project of M. de Rivaz in 1807 to the present day, which reads like an abstract of evidence tendered for the guidance of the Court in the last gas-engine patent lawsuit. In stating, however, that gas-engines have become a great commercial success "by the attention given to small

"things, in popular estimation—to important things in fact"—Sir Frederick Bramwell strains the truth in order to make it fit his own temporary requirements. Of course, a good deal of study of detail has gone to the production of the highest type of the modern gas-engine; but the success of this motor is due to insight on the part of the makers into the true conditions of their economy. The discovery of the benefit of the compression of the charges, and of the practicability of the "Otto" cycle, cannot be classed among those apparent trifles which the practical man alone knows to be important. Sir Frederick Bramwell thinks that great things are possible for vapour-engines utilizing the expansive force of vapours given off from petroleum spirits more volatile than water; but Mr. Yarrow's petroleum-vapour launches are the chief support of this idea, which has been worked upon by many skilled mechanics without much encouragement. The address also touched upon the distribution of power in towns by gas, high-pressure water, and compressed air, although in a very cursory way.

As we expected, Sir Frederick Bramwell had something to say about electric lighting; and especially in abuse of the Electric Lighting Act. He appeared in opposition to this Act when his connection with the Edison and Swan Company, which entitled him to describe himself to the Parliamentary Committee as an electrician, was a novelty; and he has never forgiven Parliament for ignoring his advice upon that occasion. He now goes so far as to assert that science has suffered from the passing of the Act in 1882, which practically forbade the lighting of districts from a central distributing station—as though it lay in the power of the British Parliament to stop the advance of science all over the world! The modification of the Act last session did not satisfy Sir Frederick; for he still regards the measure as "a great discouragement of free enterprise, and a bar to progress." There is evidently much sympathy between the two eminent brothers Bramwell; for Lord Bramwell himself could not more strenuously advocate the divine right of all persons to do just as they please without communistic reservations, than Sir Frederick Bramwell does when complaining that electricians are not in this country allowed to do what they like, as they are in the United States. Not only does he fall foul of Parliament, but the local authorities also come in for censure, because they are prone to protect themselves against the meritorious electricians who would seek to monopolize towns for their own benefit. He calls the new law a "boa-constrictor" of an Act, and waxes very indignant over the way in which it enables Englishmen to obstruct English progress in electric lighting. It is rather remarkable that he does not say one word respecting the existence of any real impediments in the path of electric lighting engineers, whether due to the low price of gas in England or otherwise. Also, as we expected, Sir Frederick Bramwell never mentioned gas lighting during the whole of his address, although, when speaking of the poetical, political, or social aspects of engineering, he might have referred (without going out of his way) to what gas has done for civilization by facilitating public meetings, rendering streets safe after nightfall, and, in short, converting the long nights of winter from their primeval gloom into opportunities for study, discussion, and social intercourse such as Rome or Athens never possessed. We do not, however, wish to find fault with Sir Frederick Bramwell for anything he did not say; for it must be generally acknowledged that the amount of information which cannot be compressed into a single address of practicable length is very voluminous. If we are to criticize the address at all, it must be on the score that what it contains is not new, and is not recounted in a very entertaining manner. Whatever explanation of Sir Frederick Bramwell's contemporary reputation is to be conveyed to posterity, his memory will owe nothing to his Bath address.

THE HALIFAX CORPORATION AND MR. W. CARR.

The attention of the Halifax Town Council is at present absorbed by what is known locally as "the gas scandal;" and there is no very clear indication as to when the end of this peculiar business is likely to be reached. The matter came before the Council at their last monthly meeting, when the Mayor (Alderman James Booth) made a statement some part of which we cannot do better than follow, almost *verbatim*, in order to show the actual state of affairs. About two months ago certain statements appeared in the *Pall Mall Gazette*, and certain letters were received by the Town Clerk, imputing the existence of malpractices in Halifax, especially in connection with the management of the Corporation gas-works. These

insinuations naturally created considerable commotion; and a Sub-Committee of the Corporation was appointed to deal with the matter. Mr. T. Fox, of the Silkstone Coal Company, came forward as the accuser, and said that he "could a tale unfold" if he were indemnified by the Corporation for the consequences of publishing his allegations. The required indemnity was readily promised; but it was subsequently discovered that the Town Council had not the power to give it, and that it must be given, if at all, by the Mayor, acting for the Corporation. When the matter was thus brought down to a semi-personal issue, however, the Mayor and his advisers of the Sub-Committee appear to have suddenly changed their minds as to the method of procedure; and instead of giving Mr. Fox the safeguard for which he had stipulated, and which was all he professed to require in order to make good his aspersions upon the management of the Gas Committee, they turned upon Mr. W. Carr, the Engineer to the Gas Department, and suggested that, as he was directly implicated in the affair, he should personally bring an action against the *Pall Mall Gazette*. Mr. Carr did not see the point thus laid before him, and "did not seem disposed to take action," as the Mayor put it. Whereupon the Mayor brought the question before the Town Council, who have unanimously agreed that Mr. W. Carr should be ordered to choose immediately between bringing his action and sending in his resignation. The Mayor was good enough to promise that, in the event of his being able to prove his innocence of the misconduct imputed to him, or fail in his case upon any merely technical point, Mr. Carr should not lose money by the proceedings. It was artfully—there is no other term for it—suggested that the circumstances connected with Mr. Carr's application for the Nottingham appointment placed a peculiar responsibility upon him in this respect. Thus the position taken up by the Mayor and the Town Council had an air of fairness imparted to it by these two considerations which, when stated in all its bareness, it conspicuously lacks. We trust that it is scarcely necessary for us to disclaim any intention to pronounce judgment in this delicate case, which in fact, if not in form, must be regarded as *sub judice*. We think it only common fairness, however, as all the Town Council of Halifax have declared against their own officer, that whatever can be advanced upon his behalf by a disinterested observer, with no more knowledge of the facts than such as may be gleaned from published reports, should be stated. The Mayor and Town Council of Halifax have ordered their Gas Engineer to choose between taking action and resignation. It is a host against one; but we declare, without reference to the merits, that the Corporation are not acting rightly in this matter. In calling upon Mr. Carr to move at this time of day, after they have dallied for months with his accuser and theirs, they have executed a manœuvre which is apparently inspired as much, if not more, by desire to save themselves money and trouble as by anxiety for a proper inquiry. We fail to find any justification now for the attempt to "put the boot upon the other leg" that would not have been more weighty in the first place than after all this coquetting with Mr. Fox. The libel printed by the *Pall Mall Gazette* remains unaltered, and to argue, as the Town Clerk did at the Council meeting, that it is made any worse or more definite because "the Committee had been told in confidence that Mr. Carr's name was 'one of three which would be mentioned,'" is a very hollow excuse for the Committee's change of front. We hold that, having begun with Mr. Fox, the Committee should either have gone on with him or have dropped him altogether, and not have trafficked with him until they got a name—it might have been of the Chairman of the Gas Committee, or of anybody else, as well as Mr. Carr—and then abandoned all idea of indemnity—because it "seemed simpler" to turn upon the individual named. Nothing that Mr. Fox or other any other informer can tell the Halifax Committee "in confidence" can implicate Mr. Carr more deeply than he was from the first by the publication of the *Pall Mall* article. If the Town Clerk said, as is reported, that at the time when the Council consulted by the Corporation gave his opinion that there was not sufficient ground for anybody to take action against the newspaper named "the world did not point to Mr. Carr, but it did now," he made a grave blunder and seriously misled the Town Council. Mr. Carr would be quite justified in declining to recognize the validity of the resolution of the Council, if his health, which is notoriously bad, permits him to take up a strong position in opposition to the Corporation. He may decline to commence an action which the legal adviser of the

Corporation has declared would be futile; and he may decline to resign his office. If the Corporation were then to remove him compulsorily, he would have his remedy in an action for wrongful dismissal. It appears to us, therefore, that the position into which the Mayor has led the Corporation is a false one, from which they should try to extricate themselves as speedily as possible.

THE ABANDONMENT OF THE PROPOSED AUTUMN MEETING OF THE GAS INSTITUTE.

A MEETING of the Council of The Gas Institute was held this day week, at which, as we are informed, it was finally decided not to hold the extraordinary general meeting in the course of the autumn which was promised in the circular issued by the President a month ago. Upon the faith of this announcement, we have lived for the past few weeks in the expectation of such a gathering of the members of the Institute to be convened some time before the winter sets in. It appears to the President and Council, however, upon fuller consideration, that much inconvenience and expense to the members generally will be saved by postponing the matters which the proposed extraordinary meeting would have had to deal with to the ordinary meeting next year. It was feared that there might be a difficulty in getting together a really representative meeting of members at the beginning of the winter season, when the responsibilities of gas managers are most harassing. This idea seems, indeed, to have prevailed extensively at the time of the previous Council meeting at which Mr. Woodall's circular was discussed; and if so, it must have been owing to some misunderstanding that the proposal to hold an extraordinary general meeting appeared as a definite promise in the circular in question. This, however, is a small matter, which affects only the President and Council. The President could call the extraordinary meeting if he chose; but he has no desire to act otherwise than with those who now share with him the responsibility of administering the affairs of the Institute. We are not disposed to question the wisdom of the decision arrived at last Tuesday; for we should be very loth to put any additional difficulty in the way of Mr. Woodall and his colleagues of the Council, who will have as much as they can do to right the Institute by next June. They must be credited with having weighed the arguments for and against an extraordinary meeting, not only from their own individual standpoints, but also with due regard to the wishes of such of their fellow-members as they have been able to confer with; and it is to be hoped that they have decided for the best. All the same, we retain our view that it would have been much better, for the sake of having a pleasant and profitable meeting in June, if the members could have then met with a clean slate before them, and all the constitutional troubles into which the Institute has drifted behind them. In deciding against this view, the President and Council have deliberately reserved a vexatious and delicate business for the general assembly, where it may possibly be disposed of with ease and celerity, or, on the other hand, may effectually wreck the meeting. They have taken the risk, however, and must now abide by the issue. There is one aspect of the subject which requires a word of comment. The President has asked those members who sympathize with the retired office-bearers, to abstain from following them until he can bring out his plans for dealing with the emergency. If this had been the programme for an autumn meeting, the business would have been settled one way or the other during the current year; and members would have been able to express their contentment with the solution, or the reverse, by renewing their subscriptions or notifying their intention to withdraw. Now, as it appears to us, the President must trust still more to the goodwill and confidence of members by asking them—in fact, if not in words—to continue their membership for another year, in the faith that he will be able to propound a cure for the evil under which the Institute now languishes. Another meeting of the Council is to be held in November, after which it is, of course, possible that a statement of policy will be issued. It may be said, indeed, that in discountenancing a general meeting before present subscriptions have run out, the Council owe to their constituents an explanation of what they propose should be done in June, in order that members may determine whether to renew their subscriptions or not. Nobody outside the Council, it may be presumed, knows what is likely to be recommended; and although members may agree to wait until November, by that time the Council should have their policy ready, and publish it in order that the proceedings at the meeting in June may be well considered and final in their effects.

Water and Sanitary Affairs.

Just before concluding his presidential address at the meeting of the British Association at Bath last week, Sir Frederick Bramwell made reference to the water supply of towns, as forming one of the topics available for the "Eulogy of the Civil Engineer." Certainly, a matter so important in its bearing on the public health could not be classed as one of the "Next-to-Nothing" series, constituting the other part of the presidential harangue, unless attention were limited to the presence of the micro-organisms, to which, as it happened, no allusion at all was made. The remarks offered by Sir Frederick showed that he considered the skill of the engineer to be specially taxed when a volume of rain water had to be stored for the supply of a large town. Meteorological considerations entered into the problem, and "huge reservoirs" had to be provided, so as to meet the contingency of three dry years occurring in succession. Fortunately, London makes no such demand on engineering skill, and is independent of any deficiency of rainfall. Whether the summer be a wet or a dry one, the Metropolitan consumer has perfect confidence that the requisite supply of water will reach him. If the water-works of the Metropolis are less imposing in their appearance than those belonging to some of our northern towns, they have the merit of meeting an enormous demand, created by a population of nearly $5\frac{1}{2}$ millions. Such an achievement, we think, might have met with a more distinct acknowledgment from Sir F. Bramwell, unless this distinguished Engineer bears in mind that London refused the benefit of his own particular scheme, proposed some years ago, whereby a second set of mains was to be placed in the streets, for the purpose of laying-on a special drinking supply. No doubt, the great engineers of the day would very much like to construct enormous reservoirs and gigantic aqueducts, to take the place of the existing works. But the humbler means may suffice. Certainty is essential in respect to the water supply of a great city; and this guarantee will be altogether wanting in the case of the Metropolis, if London is to be made dependent on a flow of water along an artificial conduit traversing a considerable stretch of open country.

Passing from the presidential address at Bath to the sectional papers, we find Mr. J. Bailey Denton proposing to replenish the underground waters of the permeable formations of England, by means of shafts to be sunk down to the line of saturation in the water-bearing strata. As concerns London, it is proposed that, whenever the Thames rises above a certain height, the superfluous water shall be diverted out of the river course on to filter-beds formed near at hand. After being freed from flocculent matter, the water is to pass down through steined shafts or sumps, so as to reach the water-level beneath. If this scheme would prevent floods, it would be a blessing to a good many owners and occupiers of land in the Thames valley above London. Otherwise it seems very like throwing away good water on the merest chance of ever seeing it again. So far as the underground waters are concerned, we think they might be left to take care of themselves. But if the project is to prevent floods in the Thames valley, let it be understood as such, though we rather fear the floods will prove too much for the sumps. As for the Metropolitan Water Supply, the probability of its being benefited by the proposed arrangement seems rather remote. Mr. Bailey Denton expects by his plan to store the flood waters—or some part thereof—underground, so as to replenish the river at Kingston when it has a tendency to run low. The propounder of this scheme is a clever Engineer; but it seems to us that the extra dose given to the subterranean regions will have gone out of reach by the time the river at Kingston stands in need of it. No doubt, a large quantity of water runs to waste in the Thames Valley during periods of heavy and continuous rain. For the mischief done by the Thames floods, we fear Mr. Bailey Denton himself, or others in his profession, must be held somewhat responsible; the extension of agricultural drainage having the effect of hastening the passage of the rainfall to the river and to the sea. First to create a flood, and then to cure it, may accordingly enter into "the eulogy," or otherwise, of the civil engineer.

A VACANCY has been created in the managership of the Maryport Gas-Works by the appointment of Mr. D. Irving to be Engineer of the Stapleton Road works of the Bristol United Gas Company. There were more than 70 applicants for the post. Mr. Irving was formerly under Mr. J. Hepworth at the Carlisle Gas-Works.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 478.)

DURING the past week there has been quite a revival of business on the Stock Exchange—to an extent unusual in the dead season; and the general tendency has been good all round. The Funds have been fairly steady; the Foreign Market undisturbed by forebodings as to a rupture of the peace on the Continent; and Railways have been buoyant upon improved returns. Even Transatlantic Rails have had a better time. The Money Market shows no change; and the existing rate seems good enough to last some while longer yet. The Gas Market has been only moderately active; but several changes in the quotations have taken place, and they are all in the upward direction—with the one exception of Gaslight "A." It opened firmly enough, and was marked on Monday at 257—the top price; but from that it gradually eased off to 254, the nominal quotation showing a drop of 1 for the week. The 10 per cent. preferences, however, have been in good demand, and exhibit an improvement of 2. South Metropolitan have been very quiet. The "B" stock has improved $1\frac{1}{2}$; but the "A" has been left standing. At existing prices it will bear a rise; and the "C" is decidedly too low. If there were any business in it, it should stand 5 higher. The prospect of the improved dividend has worked a further advance in Commercial; the old stock gaining 6, and the new stock 3. Some little business has been done in them at good figures. Of the Provincial Companies, Alliance and Dublin old has recovered the slight abatement it suffered three weeks ago; but the new stock is unchanged. British has gained 1 more; and it can hardly be bought to return $4\frac{3}{4}$ per cent. for money. All the Provincial and Suburban Companies, in fact, are well up in price. Of the Foreign undertakings, Imperial Continental is a little firmer, and marks an advance of 1. Buenos Ayres has been in good demand, and has risen 1, which is a 10 per cent. improvement on the £10 shares. All other issues dealt in show general firmness; but their quotations remain unchanged. The Water department has been very quiet, but all the Companies stand very firm; and though the old quotations are left undisturbed, the transactions marked have been at high figures.

The daily operations were: Moderate business in Gas on Monday, with firmness throughout. Commercial old rose 5; and the new, 2. Business in Water was confined to Lambeths. Tuesday's Gas business was mostly in Gaslight "A," which began to get easier. The 10 per cent. preferences, however, rose 2; South Metropolitan "B," $1\frac{1}{2}$; Commercial 1 more each; and Buenos Ayres, $\frac{1}{2}$. Nothing was done in Water. On Wednesday, Gaslight "A" and Imperial Continental were the most dealt in. The former fell 1, and the latter rose 1. Buenos Ayres advanced another $\frac{1}{2}$. Water business was all in West Middlesex, which was done at top price. Thursday was very quiet. British Gas rose 1, and Alliance and Dublin, $\frac{1}{2}$. In Water, West Middlesex again marked top price. Gas was more active on Friday, without any further change; and Water presented nothing for remark. Very little business on Saturday was done in Gas, and none at all in Water. All quotations remained unvaried.

ELECTRIC LIGHTING MEMORANDA.

ELECTRIC LIGHTING AT THE BRITISH ASSOCIATION MEETING—MR. PREECE'S ESTIMATE OF THE COST OF ELECTRIC LIGHTING—THE ELECTRIC LIGHTING OF BARNET: FANCIES ILLUSTRATED BY FACTS.

ELECTRIC lighting has had very good advertisement at the British Association meeting. Sir Frederick Bramwell, the President, dragged a condemnation of the Electric Lighting Act into his Inaugural Address; but he did not say anything very definite about the application of electricity to lighting purposes. This topic was left to the inevitable Mr. W. H. Preece, the President of the Mechanical Section, who discussed it with ardour. Everybody knows who and what Mr. Preece is—or it is not his fault—and we know in advance the tenor of what he is likely to say about electric lighting. We are compelled to state, however, that if Mr. Preece's latest utterances upon the subject of electric lighting are of the character that was to have been expected from him in his self-appointed office of high-priest of the new *cultus*, their quality shows a sad falling off even from that of the papers and speeches of a year or two ago, in which the Chief Electrician to the Post Office used to narrate how he had triumphantly adapted electric lights for the decoration of a doll's house. One paragraph of the Presidential Address with which Mr. Preece regaled his section may be cited to prove the truth of this allegation. He said that "electric lighting has become popular, not alone from the beauty of the light itself, but from its great hygienic qualities in maintaining the purity and coolness of the air we breathe. The electric light need not be more brilliant than gas; but it must be more healthy. It need not be cooler than a wax candle; but it must be brighter, steadier, and more pleasant to the eye. In fact, it can be rendered the most perfect artificial illuminant at our disposal; for it can illumine a room without being seen directly by the eye; it can be made absolutely steady and uniform without irritating the retina; it does not poison the air by carbonic acid and carbonic oxide, or dirty the decorations by depositing unconsumed carbon; it does not destroy books or articles of vertu and art by forming water which absorbs sulphur acids; and it does not unnecessarily heat the room." Mr. Preece's multitudinous labours evidently prevent him

from paying attention to the refinements of literary style, for more slipshod diction than this is seldom found in the pronouncements of English men of science. Apart from the demerits of the composition, however, its matter is illogical and for the most part rubbishy. How can electric lamps possess "hygienic qualities," for example, which assist it in "maintaining the purity and coolness" of air? They are neither made of ice, nor of disinfectants. Why, again, "must" electric lamps be more healthy than gas? And are these the only lights that can "illumine a room without being seen directly by the eye, or can be made" absolutely steady and "uniform"? What has the "irritation of the retina" to do with the precautions for rendering lights steady? Here Mr. Preece's method of expression is desperately at fault; for his words read as though he meant to say that the retina is so interested in having lights jerky and irregular, that it is difficult to make them steady without "irritating" it, except only in the case of electric lamps. Mr. Preece talked a good deal more nonsense about electric lighting, which we cannot follow in detail. He declared that in the Central Post-Office Savings Bank in London, electric lighting has saved £640 a year in the improved health of the staff. As he was compelled to admit that the installation cost £3349 to lay down, and £1034 a year in working, against £700 a year previously paid for gas, it is easy to see why he was anxious to show a saving somewhere.

Perhaps the most interesting part of Mr. Preece's address, however, was his statement of the cost of electrical and other forms of power. He said that the actual cost of production of one candle light per annum of 1000 hours is at present, for London, as follows:—Sperm candles, 8s. 6d.; gas, 1s. 3d.; petroleum, 8d.; electricity (incandescent), 9d.; electricity (arc), 1½d. This is an amazing computation; and we do not hesitate to characterize it as misleading. It is prefaced by a hasty sort of explanation, in which it is asserted that the cost of producing electricity for lighting purposes by steam is 3d. per Board of Trade unit. The charge for supplying current by the Grosvenor Gallery Company is stated at 7½d. per unit, which at the usual valuation of a unit being equal to 100 cubic feet of common coal gas, is equivalent to a charge for the same gas of 6s. 0¾d. per 1000 cubic feet. Seeing that gas is to be had in the Grosvenor Gallery district for less than half this rate, it is a mystery how Mr. Preece can bring out his calculation that gas is 75 per cent. dearer in use than incandescent light. Taking his statement in another way, by his own showing in another part of the address a candle power developed in an incandescent electric lamp absorbs 3 watts of current. A 16-candle lamp will, therefore, require 48 watts of current—say 50 for the sake of simplicity of calculation. Twenty of these lamps may be supplied for an hour, at the rate of charge of the Grosvenor Gallery Company, for 7½d. Twenty gas lamps of equal power would consume, if Argands of the standard pattern, 100 cubic feet of gas in the same time; and this would cost, including meter-rent, rather less than 3½d. Or, as Mr. Preece of course takes the best possible results for electric lighting, although he does not say where the figures given in his statement may be proved by examination of actual working, we will claim the liberty of accommodating the calculation to the results of burning gas in regenerative lamps, which can now be had of any respectable gas-fitter; and it will then appear that the consumption of gas falls to one-half, as compared with the London Argand. Hence we say that what the Grosvenor Gallery Company charge 7½d. for, can be supplied by gas consumed by means of regenerative lamps for something like 1½d., or rather less. If we are wrong, we can be corrected. Mr. Preece perhaps thinks that he occupies a position that enables him to say anything he pleases. So he may, provided that he does not look to be believed.

The local magnates of Barnet are pluming themselves greatly upon at last seeing the electric light in their streets. The drum electrical has been industriously thumped once more; and in various newspapers Barnet is held up as an example of "progress," which all the other benighted towns of the kingdom that retain gas in their highways should first admire, and then copy. It is ludicrous as well as sorrowful, to see how all experience goes for nothing with newspaper reporters when it is a case of a town adopting electric light for its streets. There is held to be something meritorious in the mere alteration from one system of lighting to the other; and such trivial details as questions of cost and efficiency are held to be irrelevant to the merits of the case. How else can one explain the fact that Barnet is loudly proclaimed in a London daily paper to have "shown a bold lead, and set an honourable example worthy of extensive imitation," merely because the Local Board have done over again what the great majority of local authorities all over the country have done before them at different times during the last six years, and have repented of sooner or later. One would think, from all the crowding of the electricians and their faithful friends of the press over little Barnet, that this is the first experiment in electric lighting that was ever heard of in the land, instead of being the last. Meanwhile, local opinion is greatly exercised upon the point whether the Local Board have done wisely or made a foolish exchange of old lights for new ones. The electrical contractor has replaced 104 gas-lamps, costing £342 per annum, with 71 electric lamps costing £383, and an extra charge for all-night lighting not yet ascertained. The people are asking themselves where is the gain of the exchange; and the local newspaper declares it to be "questionable whether the general effect of the electric light in our streets is such as to entitle it to claim superiority over that which it has replaced." It is further remarked that the ratepayers "welcomed

the electric light because they were led to believe that gas could be replaced lamp for lamp by electric light of equal power and at less cost. The fallacy of that belief is now apparent." Poor rate-payers of Barnet! They should turn for comfort to the declarations of Mr. Preece above cited, where they will learn that electric lighting ought to be cheaper than gas, if unfortunately it is not as a matter of fact. What a commentary, however, is this experience of the Barnet people upon electricians' promises; and how it shows up the real value of electrical "progress" when brought down to the level of hard cash.

THE DISTRIBUTION OF MOTIVE POWER.

THE distribution of motive power from central stations to subscriber's houses forms the subject of an interesting article by M. Ph. Delahaye in a recent number of the *Revue Industrielle*, in which the writer comments upon the various systems whereby this service is effected. The topic is one that constantly reappears in the pages of scientific journals; being, like technical education, something that can be talked and written about without fear of injury to theories by contact with too many inconvenient facts. It is a question that is capable of being regarded from different standpoints. The social reformer looks at it as offering a promise of the gradual abolition of the factory system (which may be described as that of bringing the workpeople to the centre of power) by distributing the power to the workpeople in their homes. More practically, it is regarded as a plan whereby certain undertakings for the public supply of fuel and force in different forms may supplement their principal sources of revenue. It is between these extremes that there is a wide range of debateable land, upon which the general question may be discussed from all sides.

As M. Delahaye remarks, the proposal to distribute power from house to house has been reinforced of late, as a practical question, by two or three new processes, which increase to at least six the number of systems available for the purpose in towns of any importance. The most extended of all these is certainly gas; for it is applicable wherever there is a great or a little gas-works. Water, M. Delahaye thinks, may render analogous services in certain privileged countries, as, for example, in Switzerland. Compressed air he only knows of in Paris; and the same is remarked of rarefied air. But it is stated that the existing installations of these systems are not likely to find imitators. Steam is employed in New York, and hot water in Boston; or at least there exist in these places systems of distribution of steam and hot water capable of being utilized for the production of power. And, finally, electricity is beginning to appear as a rival to the gas-engine, and may be made to serve a great number of industrial uses. M. Delahaye observes that means are therefore not lacking for the solution of a problem to which certain philosophers are pleased to attribute considerable importance in respect of its bearing upon the lot of the workman. It would be possible to say a great deal upon this part of the subject, in which praiseworthy intentions take the place of reasons; but it will be better for the immediate purpose to take note of the results of experience. American electric lighting companies are endeavouring to foster the general use of electric motors to utilize during the daytime the resources of their lighting stations. In most of the principal cities of the United States, there are to be found workshops, warehouses, and private residences, lit by electricity, in which electrically-driven tools, lifts, pumps, &c., are found to be very convenient indeed. Considering American habits, M. Delahaye thinks that these small installations are likely to multiply, since electricity is more convenient to use in this way than either steam or gas. It only requires a very small space, spares the trouble and dangers of coal or gas, and reduces the amount of supervision required to the lubrication of the journals. Those electric lighting stations that are already organized, therefore, find among their subscribers a new field for expansion which they are not likely to neglect. It appears that this example is probably soon to be followed in Berlin, where some electric lighting speculators are offering special terms to those of their subscribers who will use electro-motors. They offer supplies of current for machines of this type varying in power from 5 kilogramme-metres to 12-horse power; and thus meet the requirements of many industries. The smallest motors are to be supplied with one ampère of current; while the largest will take 105 ampères. Calculating upon the basis of a working year of 3000 hours, the cost of a horse power per hour under this system would vary from 0.575 franc with the smallest motors to 0.325 franc with the largest. For 2-horse power motors, which may be taken as the mean, the horse power would cost about 0.35 franc (3½d.) per hour.

M. Delahaye proceeds to state the comparative cost of power obtained from gas, after an experience of at least twelve years with good and economical motors. Last year the Paris Gas Company estimated that they sold 2,300,000 cubic metres of gas for the production of power. The number of engines and their power are not stated; but M. Delahaye thinks this may be safely taken at about 2500-horse power in all. The average consumption of gas per horse power per annum is, therefore, from 900 to 1000 cubic metres (35,315 cubic feet). Taking account of the average daily production of gas from the works of the Company, it does not appear that the demand for motive power exceeds 1 per cent. of the total output, or 4 per cent. of the day sales. At Marseilles, in 1887, it is reckoned that gas-engines amounting to 308-horse power were in use; consuming nearly the above stated average of 1000 cubic metres of gas per horse power per annum. Upon the total production of gas, the proportion required for motive power was a

little more than 2 per cent. At Brussels 134 gas-engines are returned as being in use; but their power is not given. They consume about 2.5 per cent. of the total production. With regard to these large towns, therefore, M. Delahaye concludes that the benefits of the distribution of power from house to house have not been much appreciated, to judge from the small proportion of consumers for this purpose. It is remarked that particulars relating to small towns are wanting; but that from such as are available it is proved that the general estimate of a consumption of 1000 cubic metres of gas per horse power per annum, is not far out of the way. Substituting English equivalents for these figures, it follows that in the ordinary way every horse power of energy developed by gas-engines, taking one with another, demands the consumption of about 35,000 cubic feet of gas per annum, bringing in, at the very common price of 2s. 6d. per 1000 cubic feet, a revenue of £4 7s. 6d. a year to the gas undertaking. Thus every horse power of energy developed by a gas-engine in regular work means as much rental to the suppliers of the gas as a large gas kitchen.

Thus far M. Delahaye, who, having brought out the facts of the average consumption of gas by a gas-engine, carries the subject no further. The question is, however, if with the twelve years' experience with the good machines of which he speaks, the results signalized by the Paris Gas Company are to be taken as representing what the electrical distribution of force may amount to in as many years. If, in short, electric lighting companies can only expect, after a dozen years' experience, to sell 1 per cent., or at most (as in Brussels), 2.5 per cent. of their output for motive power, it is hardly worth while for them to take any trouble in this matter. It is practically impossible in most English gas undertakings for the supply of motive power gas to be distinguished from that for gas cooking and heating stoves and for other industrial purposes; but we are of opinion that, if correct particulars could be ascertained, the average rate of Brussels would not be exceeded in many English towns—that is to say, we do not expect that many English gas undertakings send out much more than 2½ per cent. of their total production to be consumed in gas-engines. It may be said, therefore, from the bare figures, that the demand for gas for motive power is insignificant from a commercial point of view; and some people might be disposed to argue therefrom that, consequently, the whole question of distributing power from house to house is hardly worth talking about under present conditions.

This would be, however, a hasty and misleading conclusion from the evidence. There is a good deal to be done in the matter of distributing power in towns, the possibilities of which have only as yet been very superficially tested. When a matter of this kind is once started, nobody can tell what developments are given to it in the fierce competition of modern commercial and industrial life. The manager of a large gas undertaking may flatter himself that he knows a great deal about the capabilities of the commodity which he sells; but he would be astonished at some of the uses to which his gas is put after it leaves a few of the consumers' meters in the district. The indirect results of some of these industrial uses of gas are extraordinary as well as weighty. It is the same with other kinds of power distribution. An experienced person remarked only a short time ago, with regard to the proceedings of the companies that are now engaged in distributing hydraulic power in London and other English centres of population and trade, that they had materially enhanced the value of house property in the areas served by them. This somewhat striking result of power distribution is traceable to several causes; prominent among them being the facility afforded by a handy supply of safe motor power for carrying on a greater variety of trades in a given district than could be possible without this advantage. There are many modern callings for which a reliable, if small, supply of power is either absolutely necessary or of great advantage; and without hydraulic or gas power, it would be impossible to carry on these resources in some crowded city-districts. With these, however, manufacturers requiring power are able to compete with others for central situations in which to carry on their business; and this competition forces up rents. It is profitable for a gas company to serve a gas-engine belonging to a manufacturer of this stamp, moreover; for although the consumption of gas in the engine itself may not be large, it entails the consumption of a great deal more gas in workshops kept going by means of this power. From this single illustration, it will be seen how difficult it is to set bounds to the influence of a development in the direction of the utilization of power distributed from a central source.

American experience has been cited by M. Delahaye; but there are many reasons why the demand of householders in the United States cities, especially of the Northern States, for a supply of electrical power, chiefly as being more convenient than gas or hydraulic power, is to be regarded as exceptional. In England and on the Continent of Europe, it will be a very long time before mechanical power is required for anything but industrial and mercantile purposes, with the exception, of course, of such domiciliary establishments as hotels, clubs, and similar communistic interiors. In the States, on the other hand, progress in the direction of the domestication of machinery is marked. There are many causes for this. The great domestic servant difficulty, which dominates so much of the inside of American life, is largely instrumental in favouring the substitution of machine for hand labour for blacking boots, washing dishes, and other domestic work. If an inventor could bring out a machine which would do all the drudgery of a household by merely pulling out a series of knobs which could be reached by the mistress from her rocking-chair, he would make a

rapid fortune in the States, however high-priced his machines. There is plenty of money over there; but very little home comfort, according to the old-fashioned standards of European nations. So far have matters gone already in the way of remodelling manners of living, to suit the conditions imposed by the domestic servant difficulty, and the trouble-hating disposition of householders, that a description of a typical American house and the way of living in it generally appears utterly strange to English readers, who find their own language made unintelligible by fresh meanings imported into it with relation to common things. The wealthier class of Americans have tried to return to the soil, and to copy the peculiarly English institution of the "county family;" but have failed. They find nothing pleasing in the country, after spending much money in the establishment of country seats; and so they return to the towns, flying to the seaside, the mountain, or the lake only for a brief holiday in summer, like any worker. This peculiar feature of American life comes out very strikingly in a lecture on "Sanitary Science" recently delivered by Mrs. R. H. Richards, before the Franklin Institute. The lecturer remarked, "If the question were put to us now and here, Would you rather live to three-score and ten, but live half a mile from any neighbour, and twenty miles from any city, or would you rather take the chance of losing one-third of the time, and live in the midst of the dust and confusion which necessarily attend the passage of the rapidly-rolling wheels of modern progress?" who of us would not say 'Let me live while I do live.' The utter unconsciousness herein displayed of any possibility of living comfortably away from towns strikes an English reader with painful emphasis. Without going into the discussion of this question, however, for which these columns are unfitted, we are justified in citing Mr. Richards' remarks as evidence of a tendency to crowd into towns, which (with other things) makes Americans more suitable customers for electrical power suppliers, steam heating companies, and other agencies for relieving people of trouble and responsibility in the management of their households than can be found on this side of the Atlantic.

With this observation, we bring the present article to a close, repeating the main argument which we have desired to enforce—namely, that the consumption of gas for motive power should not be despised because it may appear a small thing in itself. It may have large incidental results, and its developments are too wide even now to be comprehended at a glance by the best informed expert.

THE GLASGOW INTERNATIONAL EXHIBITION. NINTH ARTICLE.

SUCH persons as use malleable iron and steel tubes for carrying gas, steam, or water will doubtless be much interested by the extensive and splendid collection of exhibits at the stand of Messrs. A. and J. Stewart, of Glasgow and Coatbridge. It occupies a prominent position at the end of the Machinery Court, just at the outlet to the open grounds. The collection is of a miscellaneous character, and, in every sense of the term, eminently instructive. Here one may obtain an excellent idea of the various purposes to which iron and steel tubes of the kind displayed are applied. Lap-welded tubes made of steel are placed on end; some of them measuring as high as 18 feet. Then there are some ranged horizontally, varying from 20 inches diameter and $\frac{1}{4}$ inch thick, and 8 $\frac{1}{2}$ inches diameter and $\frac{1}{4}$ inches thick, downwards. These tubes are used chiefly for hydraulic purposes, especially on board large ships of war. Amongst the fittings for boilers, there are stay-tubes, with the ends "upset" to preserve the thickness at the bottom of the thread, ferruled tubes, "Field" tubes, and tubes with copper ends; together with samples of tubes expanded and crushed cold, so as to show the quality of material used, and the soundness of the welding. There are numerous varieties of screwed and coupled tubes, such as are used for gas-services, &c., as also tubes with special screwed joints, which are tested up to a pressure of 1800 lbs. per square inch. Tubes of this kind are shown which were supplied by Messrs. Stewart to the British Government for the Suakim-Berber water pipe-line, and for the Russian and other mineral oil-fields. Numerous fittings are also exhibited from 12 inches diameter downwards, including several of Stewart's patent and other flanged joints; also a steel tube 9 $\frac{1}{2}$ inches diameter, $\frac{3}{4}$ inch thick, with expanded faucet formed on the end for a lead joint. These pipes are used for water-mains, where there is great pressure to be resisted. Tubes for boring purposes in water-sinking operations are seen in considerable variety, up to 12 inches in diameter, with screwed, flush, and other joints. Numerous coils of tubing are shown, one of which is square in section, and 260 feet long; another is of round section, and 200 feet long. Another is a flat coil of $\frac{1}{2}$ -inch tubing, 145 feet long; and there is a round coil of 1-inch tubing, 150 feet long. In all cases these coiled tubes are without screw joints. A very interesting feature of Messrs. Stewart's stand is a collection of specimens of water-piping in use at, and since, the time of the Roman occupation. They are of lead, stone, wood, and clay. One of the specimens is a 4-inch Roman lead water-pipe made in the year 90 A.D., and found at the villa of the Emperor Trajan, near Rome. The stone water-pipe which is exhibited is of 6 inches internal diameter, and was obtained at Manchester, where it was brought into use in the year 1808; the pressure borne by it being equal to 50 feet. An Edinburgh water-pipe, which was introduced in 1762, is of elm wood; and it had a pressure-bearing capacity of 100 to 150 feet. The pipes in the system to which this belonged were taper-jointed; and this

particular specimen has an internal diameter of 5 inches. Beside this pipe, there is a branch formed of red clay—like an ordinary drain-tile; and this is also 5 inches diameter. Lastly, close by and in comparison with these, there is shown a 9-inch steel tube, such as has been laid across the Tay Bridge, to carry water from Dundee into the village of Newport on the south side of the Tay. It has a pressure-bearing capacity of 2700 feet.

In the same department of the exhibition, there is another capital display of malleable iron and steel tubing chiefly for boiler purposes; the exhibitors being Messrs. J. Marshall and Sons, of Glasgow. It includes some of the greatest lengths that have yet been made in this country, rolled out of one strip. These specimens are shown in different diameters, and up to 30 feet in length. In addition to the usual boiler-tubes, there are also wrought-iron galvanized tubes for gas, steam, water, &c. There are likewise displayed a number of flange joints, of which Messrs. Marshall are making large quantities. By way of illustrating the character of the work done by this firm, there is on view a simple screw and socket joint, which has been tested up to a pressure of 6050 lbs. per square inch, without any kind of jointing material whatever being used. Among the other things exhibited at this stand are bends of very thin tubes, a variety of sections of tubes, and some good examples of boiler stay-tubes, which have been thickened out of the solid at the ends by staving, so that, when screwed, they have the same effective thickness at the bottom of the thread as the body of the tube.

Immediately adjoining Messrs. Marshall's stand is that of the Broughton Copper Company, of Manchester, at which there are exhibited numerous fine specimens of copper and brass manufactures. Amongst these there are brass pump and piston rods; iron rods covered with copper and brass for engineers' use; and copper and brass rods, &c. The stand is chiefly remarkable, however, for the excellent show of seamless drawn copper and brass tubes. Some of the former are 10 inches in bore; and 24 feet long. Larger diameters, but in shorter lengths, are also shown. In seamless brass tubes there are likewise specimens of unusual diameter and length. In all respects this collection of exhibits never fails to attract attention from visitors; and it is stated that it represents a sum of about £3000.

In a different part of the exhibition buildings, but in the same branch of manufactures, there is an excellent display from the works of Messrs. Wilkes and Sons, of Birmingham. Seamless and brazed copper tubes are shown ranging from $\frac{1}{8}$ inch up to 8 inches diameter; and there are also some very large copper tubes at the same stand. At a short distance from this stand, Messrs. R. Heaton and Sons, of Birmingham, have a fine collection of tubes in brass and copper, made by an entirely new process—the patent of a Glasgow engineer. The system of manufacture, it is said, is such as to impart to the tubes a greater amount of resisting power than is possessed by ordinary tubes. There are also on show brazed brass and copper tubes, and a variety of gas-fittings. The Birmingham Battery and Metal Company show the same class of goods; and in this connection special mention may be made of their steam and gas tubing, both in brass and copper. Muntz's metal and copper tubing in considerable variety, both seamless and brazed, are to be seen at the stand of Messrs. Kidston and Co., of Glasgow. Some of the tubes are of great length without joint, and are arranged as coils, being made by Sharp's patent process.

Tubing composed of other metals is shown by Messrs. W. Stevenson and Co., of Glasgow; among their exhibits being lead pipes, composition tubes, block-tin tubes, and lead-encased block-tin tubes. Messrs. T. B. Campbell and Sons, of Glasgow, show a great variety of gas, water, and steam fittings, and lead, copper, and block-tin tubing. Lead pipes are also shown at the adjoining stand of Messrs. Locke, Blackett, and Co., of Newcastle-on-Tyne.

THE PROPOSED GAS MANAGERS' ASSOCIATION FOR THE EASTERN COUNTIES.—Mr. H. Winhurst, Gas-Works, Sleaford, the issue of whose circular suggesting the formation of a District Association of Gas Managers for the Eastern Counties was noticed in the JOURNAL for the 28th ult. (p. 369), asks that those who have not yet replied to the circular will do so by Thursday next, as it is necessary to make arrangements for the preliminary meeting at the end of the present month. We are pleased to learn of the measure of success so far assured for the scheme; and, knowing that there is a large amount of useful work to be done in the district, would urge all who are in a position so to do so, to accord their support to Mr. Winhurst and those who are working with him in the formation of the Association.

A SOUVENIR OF THE LAST MEETING OF THE GAS INSTITUTE.—The Committee of the Société Technique du Gaz en France have just forwarded to Mr. William Sugg (who rendered such signal service, in the capacity of interpreter, to the party of French gas engineers who visited England last June) six silver medals commemorative of the occasion; and have asked him to present them to Mr. Charles Gandon, as President of the Institute, to Sir Julian Goldsmid, Bart., M.P., and Mr. H. M'L. Backler, the Chairmen of the Imperial Continental Gas Association and the European Gas Company respectively (by whom the French guests were so hospitably received at the Crystal Palace banquet), to Messrs. G. C. Trewby and Geo. Livesey, in token of the pleasant and instructive visits paid by the party to the Beckton and East Greenwich Gas-Works, and to Mr. Sugg himself, not only for his services as interpreter, but for the time and trouble he devoted to conducting M. Edissen and his *confrères* from place to place about London.

Notes.

A BURNER FOR NATURAL GAS.

At length, according to the *American Manufacturer*, a burner has been brought out that will satisfactorily burn natural gas. As an illuminant hitherto, this gas has been comparatively a failure, owing to the fitfulness of its light, and the low illuminating power given by ordinary burners. The inventor of the new burner is Mr. Todd, of the Campbell Burner Company, Pittsburgh. The object to be achieved was to construct a good and simple burner for a bright and steady light, out of a gas poor in carbon. The ordinary regenerative lamps are not applicable for this purpose, because natural gas is of very unstable composition, readily decomposing with heat, and depositing its carbon in the gas-ways of the burners as hard graphite. Natural gas has been found to burn best when the air supply is heated and restricted in quantity, and the gas is kept cool. Mr. Todd's lamp is constructed upon this principle: The burner is of the Argand class, with a brass shield fixed concentrically round the body of the burner, forming an air-deflector. This shield is continued down below the ordinary chimney gallery, and terminates in a double disc of perforated brass, through which all the air for the outside and inside of the flame must pass. The air going to the outside of the flame also passes through another perforated plate at a higher level; making three plates in all, which are found sufficient with most varieties of natural gas, although more may be added if required. The object of the perforated plates is to warm the air, as well as to check its flow, by means of heat conducted down to them through the outer brass shield, which encloses the burner. Murrysville gas is poorer than that from other fields in the natural gas region; and it is burnt in a Todd lamp with four perforated rings. Under these conditions, it is claimed that it gives as much light as ordinary coal gas, or twice as much as it does when consumed in an ordinary Argand burner. It is apparently only made in one size—burning 4 cubic feet per hour, and giving a light of about 15-candle power. The lamp is reported to have had great success; 25,000 of them being in use in the natural gas region.

THE COMPOSITION OF GOOD AND BAD MORTARS.

A writer to the *Builder* remarks, with reference to the superiority of ancient to modern mortar, that in many building specifications there is no reference to the exact composition of the mortar intended to be used. The writer urges that not only should the proportions of lime and sand be stated, but also that the sand should be required to be rough and sharp; and the nature and condition of the lime should be specified, with a limit to the quantity existing in the state of carbonate. The object of this latter restriction is to ensure the lime being well burnt. As an example of good mortar is cited that used in the building of St. Mary's Church, Illingworth, Halifax, where the walls, 2 feet thick, are built with the faces only in mortar, the interior of the wall being in dry stone, with a through header at intervals. These walls were built in 1777; and the composition of the mortar is compared with that of a soft and crumbling mortar taken from a garden wall said to be 200 years' old.

	Good Mortar.	Poor Mortar.
Water, lost at 212° Fahr.	1.64	1.66
Loss on ignition	2.59	3.06
Lime	28.50	24.75
Magnesia61	.19
Oxides of iron and alumina	3.45	2.35
Potash33	.09
Soda25	.16
Carbonic acid	18.80	17.13
Sulphuric acid73	.65
Chlorine05	.04
Silica (present as silicate of lime)	11.30	2.80
Insoluble siliceous matter.	31.75	47.12
	100.00	100.00

Equal to carbonate of lime 42.72 .. 38.93

It will be noticed that in the good mortar there is 11.30 per cent of silica present as silicate of lime, such as occurs in good Portland cement; whereas in the other sample there is only 2.80 per cent. The former is very hard, and difficult to separate from the stone; while the latter is soft and friable. Microscopic inspection showed that the sand in the good mortar is rough, with sharp edges; while in the other sample it is round, like sea or river sand.

THE PERMEABILITY OF CEMENT MORTARS.

In a recent number of the *Annales des Ponts et Chaussées* appears an article, by Messrs. L. Durande-Claye and P. Bebray, upon the permeability of Portland cement mortars. While conducting some experiments upon samples of cement mortar taken from various marine works in England, France, and Belgium, these Engineers discovered that all these mortars were permeable. A block of the material placed in such a position in an earthenware dish as to divide it into two compartments was rapidly penetrated by a 6 per cent. solution of magnesium sulphate poured into one of the compartments; all leakage past the block being prevented. As fast as the salt solution filtered through, it was constantly removed by a syphon, and more poured into the first compartment. After sixteen days, a crack 3 or 4 centimetres long appeared in the block of mortar; and next day another crack manifested itself—the block meanwhile swelling in the process. It was then determined to institute a number of experiments upon concrete with

clean water, chloride of magnesium solution, and magnesium sulphate solution. The arrangement finally adopted was to plug one end of a glass tube about 1½ inch diameter with the cement mortars under examination, the other end of the tube being closed with an india-rubber stopper, through which passed a tube about 40 inches long, connected with a flask of the testing solution. The cement mortar employed was composed of one of cement (by weight) to four of sand, gauged with quantities of water varying in different samples from 0.07 up to 0.12 per cent. of the total weight of the mixture. The rate of filtration in all the experiments was very rapid at first, but diminished as time went on; and finally became extremely slow. The glass tubes invariably cracked after a few days, from the swelling of the cement plugs; so that the experiments could not be long continued. Three sets of experiments were completed, in the first of which the mortar gauged with the least addition of water proved to be the least permeable. The effect of the magnesium chloride solution was much less than that of magnesium sulphate of the same strength. Analyses showed that the mortar, after having been acted upon by the latter solution, contained from 0.75 to 0.80 per cent. of sulphuric acid; and to this fact the authors are led to ascribe the occasional failure of cement concrete when saturated by salt water, for the acid combines with the lime to make solid sulphate of lime in the interior of the mass, the crystalline formation of which gives rise to considerable internal stresses, whilst the magnesia is washed out in the form of a thin, non-coherent cream.

BRICKLAYING IN FROST.

The possibility of carrying on bricklaying and mason's work in frosty weather is occasionally discussed in engineering journals, wherein it is generally regarded as a question only applying to emergency work. A statement has recently been published in the *Engineering and Building Record*, taken from a report that first appeared in a St. Louis newspaper, which goes to show that, although bricklaying is sometimes done in the latitude of St. Louis during the winter, it is much more costly than work done in milder weather. The upper part of the St. Paul *Globe* building was completed in December while the temperature ranged from - 15° to + 15° Fahr.; and the builders are of opinion that that part of the work is as sound as the rest. The bricklayers used salamanders, slaked their lime with hot water, heated the bricks, and laid them in the hot mortar. Thus good adhesion was secured before the frost could take hold upon the work. A man can only lay half as many bricks under these conditions as he can when the precautions against freezing are not required; and it is considered that alternations of frost and thaw would be more detrimental to newly-laid brickwork under any circumstances than a period of long-continued frost.

Communicated Article.

MODIFICATION OF HARCOURT'S COLOUR TEST.

By WILLIAM G. HICKS, Assistant Engineer of the Ramsgate Corporation Gas-Works.

As promised in my article appearing in last week's *JOURNAL*, I will now give a description of the modification of Harcourt's colour test which I have used with great success.

Referring to the illustrations, A is the platinized pumice bulb; B is the test-glass for sulphuretted hydrogen, with acetate of lead paper suspended in the tube 1; C is a test-glass, to be placed second in testing for ammonia and carbonic acid. It is provided with a tube 2 partly filled with beads. The rest of the apparatus is the same as Mr. Harcourt's, except the measures, which are divided into cubic centimetres.

Test for Ammonia.—Place a measured amount of standard solution of sulphuric acid (the same as is used with the bottle described in my previous communication) into the test-glasses—about two-thirds into No. 1, and one-third into No. 2 (see fig. 2). The solution put into No. 2 should be passed through the beads in the tube 2; fill up, with distilled water, if necessary; connect to the aspirator as shown; then attach the inlet of No. 1 test-glass to the tube from which the gas is issuing; and turn on the tap of the aspirator to give a very thin stream. Having allowed one litre of gas to pass, note the amount of exhaust shown by the gauge on the top of the aspirator. Now disconnect from the gas supply, and pass about 20 c.c. of air; disconnect the test-glasses; wash down the beads of No. 2; and titrate with standard solution of potash. The corrections, &c., are the same as described in the last article,

except that the exhaust in the top of the aspirator affects the volume of gas, and should be corrected for as described below.

Test for Sulphuretted Hydrogen.—A measured quantity of standard solution of acetate of lead is placed in one test-glass (B), as indicated in fig 1; and gas is aspirated through until the solution is saturated with sulphuretted hydrogen, which is shown by the lead paper suspended in the tube (Fig. 1) just turning brown at the lower edge. The amount of water let out of the aspirator having been noted, the calculation is as follows:—Say, 10 c.c. of standard lead solution was placed in the test-glass, and it required 1385 c.c. of gas to saturate it with sulphuretted hydrogen, then as 1385 : 1000 : 10 = 7.22 c.c. of sulphuretted hydrogen per litre. Now correct for temperature and pressure. A small piece of wool should be placed in the bottom of the tube 1, so as to prevent the solution from soiling the lead paper.

Test for Carbonic Acid.—Standard barium hydrate solution is placed in the test-glasses, in the same manner as described in the test for ammonia; and one litre of water is let out of the aspirator. Then 200 c.c. of air (which has been previously freed from carbonic acid by being sent through a small quantity of barium hydrate solution) is forced through. A piece of wool or other material should be placed in the outlet of the vessel containing the barium hydrate, so as to prevent any being carried forward into the test-glasses. Colour with phenol phthalein, and titrate with standard hydrochloric acid.

Carbon Bisulphide.—This test is the same as that given for sulphuretted hydrogen, only the gas is drawn through the platinized pumice bulb of Harcourt's colour test, to convert the bisulphide of carbon into sulphuretted hydrogen. The result in cubic centimetres, after correction, should be divided by two, and will then equal the volume of bisulphide of carbon in the gas.

Corrections for Exhaust, &c.—For example, suppose that we found 12.5 c.c. of carbonic acid in one litre of gas (as measured by the water let out), with the thermometer at 68° Fahr., and the barometer at 29.8 inches; and that the gauge on the aspirator showed 6½ inches exhaust on a column of water: Subtract ½ inch from the height of the barometer for this 6½ inches exhaust; then as the tabular number 956 : 1000 : 12.5 = 13.07 c.c. per litre, or 1.307 per cent.

The test solutions used for absorbing ammonia and carbonic acid should be at least 10 c.c. in excess of the amount actually required to combine with the quantity of these gases that are likely to be present.

For sulphuretted hydrogen, I find about 10 or 15 c.c. a convenient amount of acetate of lead solution; passing gas until it is saturated, as mentioned above.

The bottle described in my last communication makes a very convenient litre measure for the above tests, especially when used in conjunction with a smaller measure with finer divisions. It will be noted that the bisulphide of carbon test can be performed most accurately in a few minutes; and that, by adding 6 or 7 grains to the bisulphide of carbon found (after converting it into grains per 100 cubic feet), the operator will have the total sulphur compounds present in the purified gas.

In conclusion, I may say that this apparatus is portable, and in my opinion far superior to the old form; and I consider that the methods of using it described in this article will give the operator most accurate results.

THE South Milford Gas Company recently advertised for a Manager for their works in place of Mr. Patrick, resigned; and, out of some fifty candidates for the position, have selected Mr. W. Lister, Manager of the Denby Dale Gas-Works.

By a unanimous vote, the Rochdale Town Council last Thursday decided to increase the salaries of Mr. Tomlinson (Manager of the water-works) and Mr. Stenhouse (Chemist at the gas-works) as recommended by the Committees—the former by £50 a year, and the latter by £40.

A RECEIVING order was made by the Registrar of the Salford County Court last Friday against the late Town Clerk of Salford (Mr. John Graves), whose whereabouts are still unknown. The petitioning creditor was a lady. The sum owing—viz., £800—was trust money, which had been placed in the debtor's hands.

THE Parkes Museum have arranged for a course of twelve lectures to be delivered between Sept. 25 and Nov. 2 on subjects of special interest to those who are desirous of obtaining knowledge of the duties of Sanitary Inspectors. Only a nominal fee of 5s. will be charged for the series; the lectures are to be given on Tuesdays and Fridays at 8 p.m., at No. 74A, Margaret Street. Among the lecturers are Dr. G. V. Poore, Professor Henry Robinson, Sir Douglas Galton, Mr. Wynter Blyth, Mr. H. P. Boulnois, and Dr. Louis Parkes, who takes for his subject: "Water Supply, Drinking Water, and Pollution of Water."

In a recent issue of *Der Gastechner*, Herr E. Grahn describes a process for treating gas liquor and other ammoniacal liquids. Instead of boiling off the ammonia from the liquor by direct fire or injection of steam, the author proposes to inject a stream of air or chimney gas through the liquor, with or without simultaneous heating; and by this means to obtain the ammonia in a condition for absorption without the inconvenience caused by the presence of water of condensation. The absorption substances may be solid or liquid; and it is claimed that the process is applicable to the impregnation with ammonia of solid manures, such as superphosphate,

Technical Record.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ANNUAL MEETING IN BATH.

The Annual Meeting of the above Association commenced in Bath on Wednesday last. The proceedings opened with the usual meetings of the Council and the various Committees; and the first general meeting was held in the evening in the large Drill Hall, which was very nearly filled. Sir HENRY ROSCOE, the retiring President, occupied the chair; and after briefly addressing the assembly, resigned it to the President for the year, Sir FREDERICK J. BRAMWELL, who at once proceeded to deliver his Inaugural Address. Such portions of the address as are of special interest to our readers are given below.

The President commenced by saying that he proposed, as one of the two sections of his address, to discourse on the importance of the "next-to-nothing." The other section would embrace a eulogy of the civil engineer; and the value to science of his works. The two subjects would be mixed up in the most illogical and haphazard way throughout his address; but when he had finished it, he hoped to have convinced his hearers that there was no man who more thoroughly appreciated the high importance of the "next-to-nothing" than the civil engineer of the present day. He justified the selection of a civil engineer occasionally for the chair he occupied, because their Association was for the "advancement of science;" and for the advancement of science, it was absolutely necessary that there should be the application of science, and therefore the section which, in the Association, applied science was doing a very large share of the work of advancing science, and was fully entitled to be periodically represented in the presidency of the whole Association. Applications of science, and discoveries in pure science, acted and re-acted the one upon the other. To take an illustration: Electricity—known in its simplest form to the Greeks by the results arising from the friction on amber, and named therefrom, but afterwards produced from glass cylinder machines or from plate machines, and produced a century ago by the "influence" machine—remained, as did the discoveries of Volta and Galvani, the pursuit of but a few; and even the brilliant experiments of Davy did not suffice to give very great impetus to this branch of physical science. Ronalds, in 1823, constructed an electric telegraph. In 1837 the first commercial use was made of the telegraph; and from that time electrical science received an impulse such as it had never before experienced. Further scientific facts were discovered; and fresh applications were made of these discoveries. Few would be prepared to deny the statement that pure electrical science has received an enormous impulse, and has been advanced by the commercial application of electricity to the foregoing and to purposes of lighting. Since this latter application, scores (he might say hundreds) of acute minds had been devoted to electrical science; stimulated thereto by the possibilities and probabilities of this application. In this country, no doubt, still more would have been done if the lighting of districts from a central source of electricity had not been, since 1882, practically forbidden by the Act passed in that year. This Act had in its title the facetious statement that it was "to facilitate electric lighting," although it was an Act which, even modified as it had been this year, is still a great discouragement of free enterprise and a bar to progress. The other day a member of the House of Commons said to him: "I think it is very much to our discredit in England that we should have allowed ourselves to be outrun in the distribution of electric lighting to houses by the inhabitants of the United States and by those of other countries." Looking upon him as being one of the authors of the "facetious" Act, he (the President) thought it pertinent to quote the case of the French paricide, who, being asked what he had to say in mitigation of punishment, pleads, "Pity a poor orphan"—the paricide and the legislator being both authors of conditions of things which they affect to deplore.

Quitting electricity, Sir Frederick made an extended reference to (so-called) prime movers—considering the subject first "in the comparatively humble function of replacing that labour which might be performed by the muscular exertion of human beings." It must, he said, be agreed that all honest and useful labour is honourable; but when that labour can be carried out without the exercise of any intelligence, one cannot help feeling that the result is likely to be intellectually lowering. The introduction of prime movers as a mere substitute for unintelligent manual labour was in itself a great aid to civilization and to the raising of humanity, by rendering it very difficult, if not impossible, for a human being to obtain a livelihood by unintelligent work. In order to illustrate how a prime mover may not only be a mere substitute for muscular work, but may afford the means of attaining an end that could not by any possibility be attained by muscular exertion, no matter what money was expended, he compared a vessel propelled by oars with the modern Atlantic liner. He also took the case of a railway locomotive. Here, he remarked, we have from 400 to 600 horse-power developed in an implement which, even including its tender, does not occupy an area of more than 50 square yards, and that draws us at the rate of 60 miles an hour. Here, again, the prime mover succeeds in doing that which no expenditure of money or of life could enable us to obtain from muscular effort. Those meritorious prime movers were due to the application of science and to the labours of the civil engineer—using that term

in its full and proper sense as embracing all engineering other than military.

Having quoted the definition of the term "civil engineering" as given in the Charter of the Institution of Civil Engineers—viz., "The art of directing the great sources of power in Nature for the use and convenience of man," he asked, among all secular pursuits, could there be imagined one more vast in its scope, more beneficent, and therefore more honourable, than this? He maintained that the pursuits of civil engineering were worthy of occupying the highest intelligence, and that they are elevating and ennobling in their character. "Remember," he continued, "the kindly words of Sir Thomas Browne, who said, when condemning the uncharitable conduct of the mere bookworm, 'I make not, therefore, my head a grave but a treasury of knowledge, and study not for mine own sake only, but for those who study not for themselves.' The engineer of the present day finds that he must not make his 'head a grave,' but that, if he wishes to succeed, he must have, and must exercise scientific knowledge; and he realizes daily the truth that those who are to come after him must be trained in science, so that they may readily appreciate the full value of each scientific discovery as it is made. Thus the application of science by the engineer not only stimulates those who pursue science, but adds him to their number. Holding, as I have said I do, the view that he who displaces unintelligent labour is doing good to mankind, I claim for the unknown engineer who, in Pontus, established the first water-wheel of which we have a record, and for the equally unknown engineer who first made use of wind for a motor, the title of pioneers in the raising of the dignity of labour, by compelling the change from the non-intelligent to the intelligent. With respect to these motors—wind and water—we have two proverbs which discredit them, 'Fickle as the wind,' and 'Unstable as water.' Something more trustworthy was needed—something that we were sure of having under our hands at all times. As a result, science was applied, and the 'fire' engine, as it was first called, the 'steam' engine, as it was re-named, a form of 'heat' engine, as we now know it to be, was invented. Think of the early days of the steam-engine—the pre-Watt days. The days of Papin, Savory, Newcomen, Smeaton. Great effects were produced, no doubt, as compared with no 'fire' engine at all; effects so very marked as to extort from the French writer, Belidor, the tribute of admiration he paid to the 'fire' engine erected at the Fresnes Colliery by English engineers. A similar engine worked the pumps in York Place (now the Adelphi) for the supply of water to portions of London. We have in his work one of the very clearest accounts, illustrated by the best engravings, of the engine which had excited his admiration. These drawings show the open-topped cylinder, with condensation taking place below the piston; but with the valves worked automatically. It need hardly be said that, noteworthy as such a machine was, as compared with animal power, or with wind or water motors, it was of necessity a most wasteful instrument as regards fuel. It is difficult to conceive in these days how far years it could have been endured that at each stroke of the engine the chamber that was to receive the steam at the next stroke was carefully cooled down beforehand by a water injection. Watt, as we know, was the first to perceive, or at all events to cure, this fundamental error, which existed prior to his time in the 'fire' engine. To him we owe condensation in a separate vessel, the doing away with the open-topped cylinder, and the making the engine double-acting, the parallel motion, the governor, and the engine indicator, by which we have depicted for us the way in which the work is being performed within the cylinder. To Watt also we owe that great source of economic working—the knowledge of the expansive force of steam; and to his prescience we owe the steam-jacket, without which expansion, beyond certain limits, is practically worthless. . . . I think it is not too much to say that engineers who, since Watt's days, have produced machines of such marvellous power—and, compared with the engines of Watt's days, of so great economy—have, so far as principles are concerned, gone upon those laid down by Watt. Details of the most necessary character—necessary to enable those principles to be carried out—have, indeed, been devised since the days of Watt. Although it is still a very sad confession to have to make, that the very best of our steam-engines only utilizes about one-sixth of the work which resides (if the term may be used) in the fuel that is consumed, it is nevertheless a satisfaction to know that great economical progress has been made, and that the 6 lbs. or 7 lbs. of fuel per horse power per hour consumed by the very best engines of Watt's days, when working with the aid of condensation, is now brought down to about one-fourth of this consumption; and this in portable engines, for agricultural purposes, working without condensation—engines of small size, developing only 20 horse power. In such engines the consumption has been reduced to as little as 1·85 lbs. per brake horse power per hour, equal to 1·65 per indicated horse power."

Sir Frederick then alluded to the trials of engines at the Royal Agricultural Society's meeting at Newcastle last year, and went on to say that the engineer of the present day appreciates the value of the "next-to-nothings." Improvement in the working of engines must be sought by paying attention to the "next-to-nothings"—the farthings and pence of economic working. In the case of one engine, at the trials referred to, an excess of air was supplied, causing a percentage of loss of 6·34; and in another engine there was a deficiency of air, resulting in the production of carbonic oxide, involving a loss of 4 per cent. This was an admirable instance of the need of attention to apparently small things.

Continuing he said: I have already stated that we now know the steam-engine is really a heat-engine. At the York meeting of our Association, I ventured to predict that, unless some substantive improvement were made in the steam-engine (of which improvement, as yet, we have no notion), I believed its days for small powers were numbered, and that those who attended the centenary of the British Association in 1931 would see the present steam-engines in museums, treated as things to be respected and of antiquarian interest to the engineers of those days, such as are the open-topped steam cylinders of Newcomen and of Smeaton to ourselves. I must say I see no reason, after the seven years which have elapsed since the York meeting, to regret having made that prophecy, or to desire to withdraw it. The working of heat-engines, without the intervention of the vapour of water, by the combustion of the gases arising from coal, or from coal and from water, is now not merely an established fact, but a recognized, undoubted, and commercially economical means of obtaining motive power. Such engines, developing from 1 to 40 horse power, and worked by the ordinary gas supplied by the gas-mains, are in most extensive use in printing-works, hotels, clubs, theatres, and even in large private houses, for the working of dynamos to supply electric light. Such engines are also in use in factories, being sometimes driven by the gas obtained from "culm" and steam; and are giving forth a horse power for, it is stated, as small a consumption as 1 lb. of fuel per hour. It is hardly necessary to remind you—but let me do it—that, although the saving of $\frac{1}{2}$ lb. of fuel per horse power appears to be insignificant when stated in that bald way, one realizes that it is of the highest importance when that $\frac{1}{2}$ lb. turns out to be 33 per cent. of the whole previous consumption of one of those economical engines to which I have referred. The gas-engine is no new thing. As long ago as 1807, a M. de Rivaz proposed its use for driving a carriage on ordinary roads. For anything I know, he may not have been the first proposer. It need hardly be said that in those days he had no illuminating gas to resort to; and he proposed to employ hydrogen. A few years later a writer in *Nicholson's Journal*, in an article on "flying machines," having given the correct statement that all that is needed to make a successful machine of this description is to find a sufficiently light motor, suggests that the direction in which this may be sought is the employment of illuminating gas to operate by its explosion on the piston of an engine. The idea of the gas-engine was revived, and formed the subject of a patent by Barnett, in the year 1838. It is true this gentleman did not know very much about the subject, and that he suggested many things which, if carried out, would have resulted in the production of an engine which could not have worked; but he had an alternative proposition which would have worked. Again, in the year 1861 the matter was revived by Lenoir, and in the year 1865 by Hugon, both French inventors. Their engines obtained some considerable amount of success and notoriety, and many of them were made and used; but in the majority of cases they were discarded as wasteful and uncertain. The Institution of Civil Engineers, for example, erected a Lenoir in the year 1868 to work the ventilating-fan, but after a short time they were compelled to abandon it, and to substitute a hydraulic engine.

At the present time, as I have said, gas-engines are a great commercial success; and they have become so by the attention given to small things in popular estimation—to important things, in fact, with which, however, I must not trouble you. Messrs. Crossley Brothers who have done so much to make the gas-engine the commercial success that it is, inform me that they are prosecuting improvements in the direction of attention to detail, from which they are obtaining greatly improved results. But, looking at the wonderful petroleum industry and at the multifarious products which are obtained from the crude material, is it too much to say that there is a future for motor engines worked by the vapour of some of the more highly volatile of these products—true vapour, not a gas, but a condensable body, capable of being worked over and over again? Numbers of such engines, some of as much as 4-horse power, made by Mr. Yarrow, are now running and are apparently giving good results; certainly excellent results as regards the compactness and lightness of the machinery. For boat purposes they possess the great advantage of being got rapidly under way. I have seen one go to work within two minutes of the striking of the match to light the burner. Again, as we know, the vapour of this material has been used as a gas in engines; the motive power has been obtained by direct combustion. Having regard to such considerations, was I wrong in predicting that the heat-engine of the future will probably be one independent of the vapour of water? And, further, in these days of electrical advancement, is it too much to hope for the direct production of electricity from the combustion of fuel? As the world has become familiar with prime movers, the desire for their employment has increased. Many a householder could find useful occupation for a prime mover of $\frac{1}{4}$ or $\frac{1}{2}$ horse power, working one or two hours a day; but the economical establishment of a steam-engine is not possible until houses of very large dimensions are reached, where space exists for the engine, and where, having regard to the amount of work to be done, the incidental expenses can be borne. Where this cannot be, either the prime mover, with the advantages of its use, must be given up as a thing to be wished for but not to be procured, or recourse must be had to some other contrivance—say, to the laying on of power, in some form or another, from a central source. I have already incidentally touched upon one mode of doing this—namely, the employment of illuminating gas as the working agent in the gas-engine; but there are various other

modes, possessing their respective merits and demerits—all ingenious, all involving science in their application, and all more or less in practical use—such as the laying on of special high-pressure water, as is now being extensively practised in London, in Hull, and elsewhere. Water at 700 lbs. pressure per inch is a most convenient mode of laying on a large amount of power through comparatively small pipes. Like electricity, where, when a high electro-motive force is used, a large amount of energy may be sent through a small conductor, so with water under high pressure, the mains may be kept of reasonable diameters, without rendering them too small to transmit the power required through them. Power is also transmitted by means of compressed air—an agent which, on the score of its ability to ventilate and of its cleanliness, has much to recommend it. On the other hand, it is an agent which, having regard to the probability of the deposition of moisture in the form of “snow,” requires to be worked with judgment. Again, there is an alternative mode for the conveyance of power by the exhaustion of air—a mode which has been in practical use for over 60 years. We have also the curious system pursued at Schaffhausen, where quick-running ropes are driven by turbines, these being worked by the current of the River Rhine; and at New York and in other cities of the United States steam is laid on under the streets, so as to enable domestic steam-engines to be worked without the necessity of a boiler, a stoker, or a chimney, the steam affording also means of heating the house when needed. Lastly, there is the system of transmitting power by electricity to which I have already adverted. I was glad to learn, only the other day, that there was every hope of this power being applied to the working of an important subterranean tramway. These distributions from central sources need, as a rule, statutory powers to enable the pipes or wires to be placed under the roads; and, following the deplorable example of the Electrical Facilities Act, it is now the habit of the enlightened corporation and the enterprising town clerk of most boroughs to say to capitalists who are willing to embark their capital in the plant for the distribution of power from a central source—for their own profit, no doubt, but also, no doubt, for the good of the community: “We will oppose you in Parliament, unless you will consent that, at the end of 21 years, we may acquire compulsorily your property, and may do so, if it turns out to be remunerative, without other payment than that for the mere buildings and plant at that time existing.” This is the way English enterprise is met; and then English engineers are taunted by Englishmen—often by the very men who have had a share in making this “boa-constrictor” of a “Facilities Act”—that their energy is not to be compared with that which is to be found in the United States and other countries.

The next section of the address was devoted to heat-withdrawing engines, or “cold producers;” reference being made to the arrangement devised by Mr. Loftus Perkins. This gentleman, the President said, had lately taken up the mode of producing cold by the evaporation of ammonia; and, by improvements in detail, had succeeded in making an apparatus which, without engine or pumps, produced cold for some hours in succession, and required to put in action the preliminary combustion of only a few pounds of coke or a few feet of gas. Sir Frederick then pointed out how, as the work of the engineer grew, his needs increased. New material, or better material of the old kind, had to be found to enable him to carry out these works of greater magnitude. At the beginning of the present century, stone, brick, and timber were practically the only materials employed for standing engineering work—i.e., buildings, bridges, aqueducts, and so on; while timber, cast iron, and wrought iron were for many years the only available materials for the framing and principal parts of moving machines and engines, with the occasional use of lead for the pipes, and of copper for pipes and for boilers. As regards the cast iron, it was judged of largely by the eye. Wrought iron was also judged of by its results. Steel, again—that luxury of the days of his youth—was judged by the eye. The consequence was that anomalous results every now and then arose, to confound the person who had used the steel; and falsifying the proverb “true as steel,” steel became an object of distrust. Bessemer’s great invention of steel made by the converter, and Siemens’s invention of the open-hearth process, reacted on pure science, and set scientific men to investigate the laws which regulate the union of metals and of metalloids; and the labours of these scientific men had improved the manufacture, so that steel was now thoroughly and entirely trusted. By its aid engineering works were accomplished which, without that aid, would have been simply impossible. The Forth Bridge, the big gun, the compound armour of the ironclad with its steel face, the projectile to pierce that steel face—all equally depend upon the “truth” of steel as much as did the barely visible hair-spring of the chronometer, which enabled the longitude of the ship in which it was carried to be ascertained.

Referring to the work of the civil engineer as contributing directly to the prevention of disease, he said that in one town, about which he had full means of knowing, the report had just been made that, in the year following the completion of a comprehensive system of sewerage, the deaths from zymotic diseases had fallen from a total of 740 per annum to a total of 372—practically one-half. Had the engineer no inward satisfaction who knew that such results as these accrued from his work? “Again,” he said, “consider the magnitude and completeness of the water supply of a large town, especially a town that has to depend upon the storing-up of rain water; the provision which takes into account, not merely the variation of the different seasons of the

year, but the variation of one year from another; that, having collated all the stored-up information, determines what must be the magnitude of the reservoirs to allow for at least three consecutive dry years, such as may happen; and that finds the sites where these huge reservoirs may be safely built. All these, and many other illustrations which I could put before you, if time allowed, appear to me to afford conclusive evidence that, whether it be in the erection of the lighthouse on the lonely rock at sea; whether it be in the crossing of rivers or seas, or arms of seas, by bridges or by tunnels; whether it be the cleansing of our towns from that which is foul; whether it be the supply of pure water to every dwelling, or the distribution of light or of motive power; or whether it be in the production of the mighty ocean steamer, or in the spanning of valleys, the piercing of mountains, and affording the firm, secure road for the express train; or whether it be the encircling of the world with telegraphs—the work of the civil engineer is not of the earth earthy, is not mechanical to the exclusion of science, is not unintellectual, but is of a most beneficent nature, is consistent with true poetical feeling, and is worthy of the highest order of intellect.”

On the motion of the Mayor of Bath, seconded by Sir William Thomson, a vote of thanks was accorded to the President for his address.

MR. PREECE ON ELECTRIC LIGHTING.

At the Opening Meeting of the Mechanical Science Section of the British Association last Wednesday, the PRESIDENT (Mr. W. H. Preece, F.R.S., M. Inst. C.E.) delivered an address on the capability of electricity to minister to the wants of mankind. In his opening remarks he drew attention to its power of instantaneously transmitting intelligence to a distance by means of the telegraph and telephone; and then went on to refer to its use as a lighting agent. As this portion of his address will be of special interest to our readers, we give it *in extenso*, as follows:—

Electric lighting has become popular, not alone from the beauty of the light itself, but from its great hygienic qualities in maintaining the purity and coolness of the air we breathe. The electric light need not be more brilliant than gas; but it must be more healthy. It need not be cooler than the wax candle; but it must be brighter, steadier, and more pleasant to the eye. In fact, it can be rendered the most perfect artificial illuminant at our disposal; for it can illumine a room without being seen directly by the eye; it can be made absolutely steady and uniform without irritating the retina; it does not poison the air by carbonic acid and carbonic oxide, or dirty the decorations by depositing unconsumed carbon; it does not destroy books or articles of vertu and art by forming water which absorbs sulphur acids; and it does not unnecessarily heat the room. In our Central Savings Bank in London, it has been found, after two years’ experience of electric lighting, that the average amount of absences from illness has been diminished by about two days a year for each person on the staff. This is equivalent to a gain to the service of the time of about eight clerks in that department alone. Taking the cost at the “overtime” rate only, this would mean a saving in salaries of about £640 a year. The cost of the installation of the electric light was £3349; and the annual cost of working £700 per annum—say, a total annual cost of £1034. The cost of the gas consumed for lighting purposes was about £700 a year; so that on the whole there was a direct saving of something like £266 a year to the Government, besides the material advantage of the better work of the staff resulting from the improved atmospheric conditions under which their work is done.

The production of light by any means implies the consumption of energy; and this can be measured in watts, or the rate at which this energy is consumed. A watt is $\frac{7}{12}$ part of a horse power. It is a very convenient and sensible unit of power; and will in time replace the meaningless horse power.

One candle light maintained by tallow			absorbs	124 watts

The relative heat generation of these illuminants may be estimated from these figures.

Though the electric light was discovered by Davy in 1810, it was not until 1844 that it was introduced into our scientific laboratories by Foucault; it was not until 1878 that Jablochhoff and Brush showed how to light up our streets effectually and practically; and it was not until 1881 that Edison and Swan showed how our homes could be illuminated softly and perfectly. Unpreparedness for such a revolution produced a perfect panic among gas proprietors; inexperience in the use of powerful electric currents resulted in frequent failure and danger; speculation in financial bubbles transferred much gold from the pockets of the weak to the coffers of the unscrupulous; hasty legislation in 1882 restricted the operations of the cautious and the wise; and the prejudice arising from all these causes has, perhaps fortunately, delayed the general introduction of electricity. But now legislation has been improved, experience has been gained, confidence is being restored; and in this beautiful town of Bath fifty streets are to be lighted. We see everywhere around and about us in our English homes the pure glow lamp replacing filthy gas and stinking oil. The economical

distribution of the electric current over large areas is annually receiving a fresh impetus. The expensive systems defined in the Act of Parliament of 1882 have entirely disappeared. Hopkinson in England and Edison in America showed how a third wire reduced the weight of copper needed by 66 per cent. Gaulard and Gibbs in 1882 showed how the conversion of alternative currents of high electro-motive force to currents of low electro-motive force by simple induction coils would enable a mere telegraph wire to convey sufficient electricity to light a distant neighbourhood economically and efficiently. Lane Fox in 1879 showed how the same thing could be done by secondary batteries. Planté, Faure, Sellon, and Parker have done much to prove how batteries can be made to solve the problem of storage; while King and Edmunds have shown how the distribution by secondary batteries can be done as economically as by secondary generators. The Grosvenor Gallery Company in London have proved the practicability of the secondary generator principle by nightly supplying 24,000 glow lamps scattered over a very wide area of London. The glow lamp of Edison, which in 1881 required 5 watts per candle, has been so far improved that it now consumes but 2½ watts per candle. The dynamo, which in the same year weighed 50,000 lbs., absorbed 150-horse power, and cost £4000 for 1000 lamps, now weighs 14,000 lbs., absorbs 110-horse power, and costs £500 for the same production of external energy—in other words, its commercial output has been increased nearly six times; while its prime cost has been diminished eight times.

The steam-engine has received equal attention. The economy of the electric light when steam is used depends almost entirely on the consumption of coal. With slow-speed low-pressure engines one kilowatt—1000 watts, 1½-horse power—may consume 12 lbs. of coal per hour. In high-speed high-pressure triple-expansion engines, it need not consume more than 1 lb. of coal per hour. Willans and Robinson have actually delivered from a dynamo one kilowatt by the consumption of 2 lbs. of coal per hour, or by the condensation of 20 lbs. of steam. There is a great tendency to use small economical direct-acting engines in place of large expensive engines, which waste power in countershafting and belts. Between the energy developed in the furnace in the form of heat, and that distributed in our rooms in the form of light, there have been too many points of waste in the intermediate operations. These have now been eliminated or reduced. Electricity can now be produced by steam at 3d. per kilowatt per hour. The kilowatt-hour is the Board of Trade unit, as defined by the Act of 1882, for which the consumer of electric energy has to pay. Its production by gas-engines costs 6d. per kilowatt-hour, while by primary batteries it costs 8s. per kilowatt-hour. The Grosvenor Gallery Company supply currents at 7½d. per kilowatt-hour. A 20-candle power lamp consuming 3 watts per candle, and burning 1200 hours per annum, expends 82,000 watt-hours or 82 kilowatt-hours, and its costs, at 7½d. per unit, 50s. per annum. If the electricity be produced on the premises (as is the case in the Post-Office, in the House of Commons, and in many large places), it would cost 20s. 6d. per annum. I have found from a general average under the same circumstances, and for the same light, in the General Post-Office in London, that an electric glow lamp costs 22s., and a gas-lamp 18s. per annum. The actual cost of the production of one-candle light per annum of 1000 hours is as follows:—

Sperm candles	8s. 6d.
Gas (London)	1 3
Oil (petroleum)	0 8
Electricity, glow	0 9
„ arc	0 1½

The greatest development of the electric light has taken place on board ship. Our Admiralty have been foremost in this work. All our war-ships are gradually receiving their equipment. Our ocean-going passenger ships are also now so illumined, and perhaps it is here that the comfort, security, and true blessedness of the electric light is experienced. Railway trains are also being rapidly fitted up. The express trains to Brighton have for a long time been so lighted; and now several Northern railways—notably the Midland—are following suit. Our rocky coasts and prominent landfalls are also having their lighthouses fitted with brilliant arc lamps; the last being St. Katherine's Point in the Isle of Wight, where 60,000 candles throw bright beams over the English Channel; causing many an anxious mariner to proceed on his way rejoicing.

In the final portion of his address, Mr. Preece, among other matters, dealt with the transmission of energy by currents, the use of electricity for working tram-cars, in electro-plating, and in the fusion of metals with a high-melting point; and concluded by saying: "Five million people upon the globe are now dependent on the electric current for their daily bread. Scarcely a week passes without some fresh practical application of its principles; and we seem to be only on the shore of that sea of economy and beneficence which expands with every new discovery of the properties of electricity, and spreads already beyond the mental grasp of any one single worker."

It is stated that three million feet of gas is the lowest estimate of the flow of natural gas every twenty-four hours from the well recently finished at Sparta, Illinois. It is said that the escape is attended by a roar that can be heard at Marissa, ten miles away; and in the immediate vicinity the force exerted gives the earth a vibration similar to that noticeable in a factory building when the machinery is in motion. How to derive practical benefit from the well has not yet been decided.

THE VALUE OF GAS AS A FUEL.

Mr. J. Emerson Dowson, M. Inst. C.E., read a paper on Saturday before the Mechanical Science Section of the British Association at Bath, upon "Gaseous Fuel." In 1881, Mr. Dowson said he explained to the Association an apparatus for making cheap heating gas by passing steam and air through incandescent fuel. Since then the apparatus had been much improved, and had come into wide application for driving engines and other industrial processes. The composition of the gas necessarily depended somewhat on the quality of the coal used, and the condition of the fire; but it averaged much the same. The cost varied from 6d. to 1s. per 1000 cubic feet, according to the price of the coal. He believed he was justified in saying that gas-power was now fairly launched in competition with steam-power, and the use of gas was yearly increasing. Returns by users of "Otto" gas-engines worked by Mr. Dowson's gas showed a fuel consumption of 18 lbs. per indicated horse power per hour, which was less than half that required for the best steam-engines of equal power. Sir F. Bramwell thought it was clear they were tending in the direction of an engine in which water would not be used. To produce an arrangement which gave so low a cost per horse power as had been named was a great thing. The waste of fuel which should be the inheritance of their successors was very serious. Replying to a question, as to the danger of the poisonous carbonic oxide which formed 30 per cent. of the gas in question, Mr. Dowson said it was useless to deny that the gas was poisonous; and in that sense dangerous. But like other things, it must be used accordingly. Where preferred, as an additional precaution, a smell could be given to the gas (by which its escape might be detected) by passing it over trays of sublimed naphthalene.

COMPRESSED OIL GAS AND ITS APPLICATIONS.

In April last we published* an abstract of a paper on this subject read before the Institution of Civil Engineers by Mr. A. Ayres. By the recent issue of the usual quarterly volume of proceedings, we are now put in possession of the full text of the discussion and correspondence that followed the reading of the paper; and as it comprises a great deal of information that is both interesting and useful to gas engineers in a general sense, we propose to lay before our readers a few abstracts and comments upon the same. The appendix attached to the paper gives several statistics respecting the cost of oil gas to eight of the principal railway companies who use it, from which it appears that the annual production for the lighting of railway carriages is more than 30 million cubic feet, and the actual cost varies a great deal, but may be said to range from 8s. up to 13s. per 1000 cubic feet as delivered at the burners. There is a remarkable difference in the returns for residuals, which range from 3½d. to 1s. 10d. per 1000 cubic feet of gas made. With two exceptions, however, this item is less than 1s. The yield of gas per gallon of oil ranges from 72 to 81 cubic feet per gallon.

In the course of the discussion, Mr. Joseph Tomlinson stated that the illuminating power of gas made on the Pintsch system, speaking from the results of several years working, was 51 candles; but this was reduced by compression to the extent of 150 lbs. per square inch, to 38 candles. The compression was accompanied by the deposition of one gallon of hydrocarbon per 1000 cubic feet of gas, which he was able to sell for 2s. The average yield was 81 to 83 cubic feet per gallon. He exhibited a table showing that a great saving had been effected by introducing the Pintsch system, as compared with the uncompressed coal gas and oil-lamps formerly used; the cost being 0·21d. per lamp per hour. He introduced a small chamber of gas between the regulator and the burner, which prevented the lights being extinguished by accidental shock, &c., and enabled him to reduce them when running in open spaces by day. Mr. James Keith spoke about the apparatus bearing his name, saying that it had been designed to obtain a maximum yield of gas with a minimum consumption of fuel, and a cool and permanent gas that might be used as fast as it was made without leaving any deposit. His original single-retort apparatus with one fire, making at least 200 cubic feet of gas per hour could be heated from the cold state in 60 to 90 minutes; and a more recent four-retort apparatus, making at least 1000 cubic feet per hour, could be similarly heated up in from 3 to 4 hours. The fuel account should be much less in an oil than in a coal gas apparatus. His system was decidedly different from that of other makers; he believed in rapid making, thorough washing, and quick and thorough atmospheric cooling. The quality of the oil was an important point, and he had used a thickish blue oil that gave about 50 per cent. more gas to the gallon than ordinary paraffin oil at a less price would give; the temperature of distillation and the quality of the gas being practically the same in each case. The practicability of running gas-engines successfully by rich oil gas was first proved at the oil-gas works erected at Langness Point, Isle of Man, nine years ago. Another feature was the admixture of the 50 or 60 candle gas with air before consumption. By means of a meter-mixer a proper quantity of air was introduced to bring the quality down to the Scotch canal gas standard, which enabled it to be employed either for lighting, heating, or power, with far better results. The air-mixing apparatus could be adjusted to dilute the gas down to any desired quality, so that it could be used with any burners or fittings suitable for ordinary coal gas. The result of the dilution was a whiter, clearer, and better diffusible light, with no smoke; and when used for gas-engines the

* See JOURNAL, Vol. LI., p. 686.

air-mixing arrangement was indispensable, where regularity and reliability in running were essential.

Mr. W. H. Preece thought the discussion would not be complete without some reference to the application of electricity to some of the purposes mentioned, and believed that it would be found far more satisfactory in the future than either coal gas or oil gas. His remarks, however, consisted more of assertions than of actual practical statistics, the only reference he made to figures being the unsupported statement that electricity was cheaper than gas. If it was desired to obtain 10,000 candles by the consumption of gas, he said, it would cost 10s.; but a similar amount of light could be produced by electricity for 7s. 6d. It is surprising that Mr. Preece should have shown ignorance of the recent improvements in gas-burners, which admit of a duty of 8, 9, or 10 candles per cubic foot of gas being obtained. As a matter of fact, the cost of producing 10,000 candles by means of gas would be much less than one-half of his estimate, or about one-half of the price given by him for electricity; and this, by the way, is very much lower than other estimates, based on actual working, that have been published. Mr. Killingworth Hedges followed with some particulars of a trial of electricity on the Glasgow City District Railway, on Carswell's system, in which a central rail between the ordinary rails was provided which carried the current, and contact could be made with it any time, producing the light. The present cost was 0.4d. per lamp per hour with the engine and plant not working up to its full capacity, though if this was done it would be a great deal cheaper; while the cost of the gas supplied to the North British Railway by the Pintsch Company was 0.16d. per lamp per hour.

Mr. Charles Ingrey remarked that the paper dealt with three distinct applications of hydrocarbon oil; firstly, the generation of gas by means of gas-works, the mechanical compression of the gas so produced, and storage of the same in hermetically-sealed vessels, which could be conveyed to a distance; secondly, to the storage of the gas in gasholders, whence it could be used on the spot; and, thirdly, the supply of oil by gravitation to the burner itself. He thought that the use of compressed gas for buoys, beacons, and the like was the best system that could be adopted for that purpose, as it enabled a large quantity of light-giving power to be stored in a small compass; but it was worth consideration whether the system of generating gas from heavy oil by means of expensive gas-works was the best for driving engines or giving light. At Ailsa Craig the gas-works had cost from £3000 to £4000, and their main purpose was to drive 8-horse power engines; so it might be taken that there was a production of 32-horse power by apparatus which cost that large sum of money. Taking the author's figures, he calculated that 80 per cent. of the coal used as fuel at the oil-gas works, applied directly under a steam boiler, would give a similar amount of power without the oil and without the gas-works. He exhibited a small and comparatively cheap apparatus for producing gas on the spot, from light petroleum spirit, which he considered would prove more economical than ordinary gas-oil works.

Mr. W. Foster had examined several samples of oil gas produced under various circumstances. He found that oil gas made at low temperature contained a considerable amount of carbon vapour. By heating the oil in retorts, gas was obtained which was as high, if not higher, in illuminating value, but contained much less carbon vapour, and therefore yielded much less carbonic acid on combustion; 100 volumes of low-temperature gas would give 150 volumes of carbonic acid gas; the high-temperature gas would give considerably less. If gas were obtained by saturating air in the way intended by the use of the apparatus exhibited, the amount of carbon vapour would be very high, but the illuminating power would not increase in proportion. By the action of heat in the destructive distillation of oil, unsaturated hydrocarbons were obtained, the energy of which, as an illuminating agent, was considerable. Berthelot had shown that benzene vapour, naphthalene, acetylene, and other bodies increased the illuminating power considerably; that 3 per cent. by volume of benzene would raise a non-luminous but combustible gas to a power of 20 candles. In the case of low-temperature gas, the total amount of carbon vapour was high, and it existed largely in the form of paraffins; and by heating in a retort at still higher temperatures, such paraffins could be made to yield other substances which had a high illuminating power. With regard to the petroleum vapours, he had no doubt that the amount of carbon vapour would be found much greater than even the low-temperature gas. Connected with this subject was the question of getting more illuminating value by the action of heat in the retorts. The question had been raised whether it was worth while to use high temperatures and expensive plant. He inclined to it would be expensive to work an automatic air-machine of the kind shown, as a great deal of carbon would have to be burnt into such gas to produce anything like the high illuminating value known to obtain in the case of gas made by destructive distillation proper. He could not see how "gas" was made in such a machine. No tar was produced, and if petroleum vapour was merely passing forward without the production of tar, the first products were not being differentiated, but the spirit was merely caused to vaporize into a measured quantity of air.

Mr. Harland had worked a small oil-gas factory abroad, and experienced difficulty in the wear and tear of the wrought-iron retorts, due to the dropping of the oil. The retort speedily became pitted at the point where the oil dropped in, a hole was eaten through in a short time, and the retort spoiled. He thought that it was not necessary that tar should result from the dissociation of low-gravity oil if gas was really produced in the automatic machine,

because the oil used had been refined at least half-a-dozen times. It was a pure hydrocarbon; and whether it was destructively distilled, or merely evaporated at a high temperature, no tar could possibly result, because there were no chemical compounds in the substance likely to produce tar. So the gas produced from refined oils of low gravity was richer in illuminating power and contained less residual products than gas produced by destructive distillation in retorts at high temperatures. It appeared to him that it only required an automatic machine, or one on that principle, to produce gas not necessarily from gasoline, but from shale spirit, and other products that were drugs in the market. Mr. Rickman pointed out that no system of electricity at present known could offer the advantages secured by the compressed gas—viz., a light of not less than 10-candle power, each vehicle containing a supply for 30 to 36 hours independent of others, capable of being charged in a reasonable time, say two or three minutes, and apparatus not excessive in weight. The trials at Glasgow with the electric light referred to certain tunnels only, and if continuous illumination was wanted at night, some other system of lighting had to be used in addition. Some speakers had referred to the use of light oils; but if this meant hydrocarbons flashing at a low temperature, the use of such was dangerous and objectionable for several reasons. Mr. A. J. Hill said that the rate of production named by the author— $6\frac{1}{2}$ to 7 cubic feet per minute—was very low; but perhaps the size of the retort used would explain that statement. In his experience 20 cubic feet per minute could be produced with 10-inch retorts. He was surprised that nothing had been said in the paper or the discussion about the use of the residual products, especially tar as a fuel. At the Great Eastern works it was used under the boilers as a fuel, in combination with coal and other solid fuel, and it was a great convenience to be able to use all the tar which could not be sold as it was made.

Mr. S. R. Barrett said that the railway companies had tried gas as supplied by the gas companies, in a compressed form, enriched by means of gasoline to a quality of 40 to 50 candles; but at present only one British gas company was using it, though it had been largely adopted in Germany and America. The Jersey City Gas Company received £2000 per annum for gas supplied in a compressed form to the New York and Quaker City railways. Probably the improved systems of Messrs. Pintsch and Mr. Pope had caused its discontinuance in this country; but since then great improvements had been made in burners, and a duty of 5 candles or more per hour could be obtained from 16 candle gas. The fishtail burner was necessary for oil gas, and it obtained a very low duty from it. The gas had been improved to meet the deficiencies of the burner, rather than an endeavour made to secure a burner that would give good results with ordinary gas. The cannal gas supplied in several towns in Scotland was cheap compared with the oil gas quoted by the author, and afforded the means, in conjunction with improved burners, of obtaining a good light at a small cost. Gas of 30-candle power compressed to 90 lbs. per square inch would be reduced to 20-candle quality. Such compressed gas burnt in a regenerator burner at the rate of 3 cubic feet per hour, would give a light of 20 candles—a greatly improved light, at a cost of 0.12d. per lamp per hour, or not much more than one half of the cost of oil gas as given by Mr. Tomlinson. Ordinary coal gas had been tried with much success on the Belgian railways, in carriages adapted for the oil-gas system. It was compressed in the usual way, and each lamp was fitted with a carburetting cylinder containing naphthalene, somewhat on the principle of the alba-carbon gas-light. The gas was raised to 50-candle quality, and the carburetters only required changing once in 20 days. The consumption of the gas was 1.5 cubic feet per hour, and of naphthalene 40 grains, the light yielded being 8-candle power; and the cost, with gas at 2s. 6d. per 1000 cubic feet, was 0.05d. for gas and 0.01d. for the naphthalene, or a total of only 0.06d. per lamp per hour.

Mr. Ayres replied at length to the various observations of the speakers. He could not agree with Mr. Keith that it was advantageous to dilute gas with air before combustion. The mixture should take place at the point of combustion. He referred to the numerous precautions necessary to ensure the safe storing of even very small quantities of petroleum spirit, and did not think it admissible for ordinary lighthouse illumination. The durability of the retorts referred to in his paper was fully six months, and the oil was dropped upon sheet-iron trays and not received directly upon the floor of the retorts.

In addition to the discussion, there was also a lengthy "correspondence" on the paper. Mr. G. Beilby stated that, some years ago, he undertook a series of tests to determine the most suitable oils, and the best temperatures at which to decompose them into illuminating gas. His results were generally in accord with the conclusions of the author; and it was found that the so-called intermediate oils were very suitable. These were so called because in boiling point and specific gravity they ranked between burning oils on the one hand and lubricating oils on the other, and owing to the very limited demand for them, their price was very low, and this had no doubt helped to bring about the adoption of oil-gas lighting by the railway companies. With oils at from 3d. to 6d. per gallon, the cost of oil gas would be from 3s. to 6s. per 1000 cubic feet. Mr. C. E. Botley did not agree that the illuminating power of the gas depended more on the temperature of distillation than on the quality of the oil. Both the quality and quantity of the gas were effected by the temperature at which it was distilled from the oil; and every oil required a different treatment to obtain the best results. A fair comparison of the quality of the oil could be obtained by

multiplying the ascertained illuminating value of 1 foot consumed in a flat-flame burner, by the number of cubic feet produced from one gallon of oil. If only the actual consumption in the retort was mentioned it would give too high a result, as in practice there was a loss of about 6 lbs. per cask due to absorption, besides leakage from tanks, loss in pumping, &c. In practice he had found that the yield of gas was about 75 cubic feet per gallon of oil, and the quality after compression, from 36½ to 45 candles. The cost, with oil ranging from 3½d. to 6d. per gallon, was from 4s. 5d. to 6s. 9d. per 1000 cubic feet. After efficient condensation and scrubbing he did not consider that the gas required purifying. The loss due to compression, he said, should not exceed 10 per cent., instead of 20 per cent. as quoted by the author; and referred to results of a long series of experiments, communicated to the Southern District Association of Gas Engineers,* which showed that the lower the quality of the gas, the greater was its capacity for re-absorbing the hydrocarbon deposited in the process of compression, as the pressure was reduced, so that coal gas did not lose so much in proportion as oil gas. The value of the hydrocarbon and tar had fallen so much that the cost of producing oil gas was seriously affected. A few years ago the hydrocarbon realized 1s. 3d., and the tar over 2d. per gallon. Now only about 6d. per gallon was obtainable for the former, and the tar was unsaleable; but he had successfully applied the latter as a fuel under boilers. There would always be a loss on the gas available for lighting as compared with that measured by the station meter, due to leakage in various ways. Although oil gas on a fairly large scale was undoubtedly the best means for lighting railway carriages, still there were instances where compressed coal gas could be successfully applied. Where the cost price of the gas was taken as a comparison, there was no doubt of its being cheaper, light for light; and any system of gas lighting was more satisfactory than oil. Mr. G. Bower said that 25 years ago he supplied an oil-gas apparatus to the Indian Government, that produced continuously, in the regular course of working 100 cubic feet of gas per gallon of oil. Then in 1866 he published a description of a mode of compressing gas and applying it to the lighting of railway carriages. His son had invented a regulator that gave a constant pressure of 1 inch at the burner, no matter to what extent the pressure in the regulators might vary. Mr. H. Leicester Greville had had considerable experience in the experimental manufacture of oil gas, and found that 50-candle gas could be easily and continuously made, by the simple expedient of allowing the gas to flow down a wrought-iron pipe, carried through the mouthpiece and continued to within 6 inches of the back of the retort. (A somewhat similar plan has been tried and recommended by Mr. N. H. Humphrys).† The oil vaporized in this pipe and the vapour were decomposed in passing back in contact with the heated sides of the retort to the ascension pipe. The best heat was the ordinary temperature used at gas-works—viz., a “cherry red,” and the oil was ordinary common American petroleum. The yield was about 90 cubic feet of gas per gallon of oil, and it was improved by using a little water or steam with the oil. The quality and quantity depended on the heat of the retort and the rate at which the oil was run in; the best results following with least back pressure on the retort. The best plan for testing the rich gas was to consume it at the rate of from 1½ to 2 cubic feet per hour in a fishtail burner with fine holes, such as a No. 0 or No. 1 Bray, and then to calculate the result with a consumption of 5 cubic feet. Mr. G. M. Hunter said he thought that under ordinary circumstances the loss by compression did not exceed 10 per cent. of the illuminating power. He insisted on the necessity of a purifier, as the gas contained varying quantities of sulphur compounds and of carbonic acid. An advantage of the Pintsch system was that every stage of the manufacture was mechanically controlled, and nothing in the way of stoppage could occur without the attention of the attendant being directed to the place. He objected to the arrangement in Pope’s apparatus, which allowed the oil to enter the hotter retort first, and the gas to pass out through the colder retort. The gas could not be benefited by passing through the colder retort, and a larger consumption of fuel would also be necessary. In the Pintsch apparatus a contrary course was followed; the gas passing through a length of 11 ft. 8 in. of heated retort, and thus being thoroughly fixed. Mr. F. J. Rowan was more particularly interested in the application of oil gas without compression, as it afforded an outlet for intermediate oils and other products, and also being intimately connected with the subject of liquid fuel. He referred to the system of manufacture adopted by Mr. Rogers, at Watford, which consisted of injecting oil into red-hot retorts by means of steam jets. This prevented to a great extent the deposition of solid carbon in the retorts; and the steam could conveniently be raised by means of the waste heat from the retort furnace. The result was a much higher yield than that afforded by the Pintsch or other systems. Mr. J. R. Wigham preferred gas from rich cannel coal to oil gas, and believed it would be more advantageous, for all the purposes named by the author, to compress ordinary coal gas, which was much cheaper and more easily obtained than oil gas. The same illuminating power could be obtained by the aid of modern improved burners. He regarded the method adopted at Ailsa Craig, of making oil gas and then diluting it with air, as a clumsy and extravagant mode of procedure.

MR. LEWIS T. WRIGHT left England last Wednesday to take up his new appointment as Engineer and Manager of the Buenos Ayres New Gas Company.

Register of Patents.

PLATINUM-GAUZE INCANDESCENT GAS-BURNERS.—Lewis, J., of Tottenham.

No. 13,511; Oct. 5, 1887. [8d.]

This invention relates to the arrangement and construction of gas-burners for consuming a mixture of gas and air supplied to the burner under pressure; the combustion of the gas and air causing a cap of platinum-wire gauze or other suitable metal on the end of the burner to become incandescent.

In the illustration, A is the cap of wire gauze (made of platinum or other suitable metal or mixture of metals) mounted upon a tube filled with a number of smaller tubes through which the mixture of air and gas passes from the space or chamber below into the cap for combustion. These small tubes merely serve to prevent the gas-flame from firing back into the chamber, and thus causing explosion. Below this again is a ring of metal, so inserted as to fill up the space between the inner surface of the top tube and the end of the supply-pipe B, upon which it fits so as to conduct the mixture of gas and air to the burner. A reel or sleeve of steatite or other suitable non-conducting material connects the top end of the supply-pipe B to the lower portion thereof, and prevents the transmission of heat from the burner to the pipe. Each end of the reel is formed slightly conical internally; and the ends of the pipes inserted therein are formed with a corresponding male cone, so arranged as to leave a space between the two ends where they approach one another. X are branch-tubes, through which induced currents of air are drawn in by the current of compressed air as it issues from the nozzle of the pipe C. The main pipe is connected to the end of the pipe D, into which gas is admitted by the branch-pipe E, from which it passes through the annular space around the pipe C, and is mixed with the air from the pipes X and C in its passage to the burner. The end of the pipe C is fitted into, and surrounded by the end of the pipe D.

CARBURETTING AIR AND ENRICHING GAS.—Herzog, C., of Queen Victoria Street, London. No. 1018; Jan. 23, 1888. [8d.]

The apparatus shown in the engraving is intended for carburetting air for lighting and heating purposes, and for enriching gas poor in carbon—figs. 1 and 2 being an elevation and plan of the general arrangement; and figs. 3 and 4, a vertical section and plan of the carburetting chamber.

In the chamber A (preferably of cylindrical shape) there are placed a number of superposed trays or dishes B to contain gasoline or other hydrocarbon fluid. The trays are supported within the cylinder upon two semicircular pieces C, held in their proper relative positions by the rod D; and they are provided with openings E at opposite sides of the trays, so that the air or gas is caused to pass through the apparatus in a circuitous direction, and is thus brought into contact with a large surface of hydrocarbon. The upper tray is provided with a filling

opening F; or it is connected with a reservoir of hydrocarbon located outside the building in which the apparatus is fixed. The hydrocarbon as it overflows from the upper tray falls into those below it; and the surplus flowing from the bottom tray of the apparatus is drawn off from time to time through a cock G.

The means for causing the passage of air or gas through the chamber A comprise two collapsible chambers, H, secured at their lower ends to circular bases I, and at their upper ends to the discs J; the interiors of the casings being adapted to be placed in communication with the carburetting chamber through a three-way cock J. The chambers (preferably constructed of waterproofed cloth) when expanded are adapted to be filled with air or gas from any suitable source. Then, as the casing collapses or becomes shorter—owing to its weight or to auxiliary weights K—the air or gas therein is forced through the pipe L into the carburetting chamber; and from the latter the carburetted air is forced through the pipe M to the points where it is required for use. N are counterweights connected by chains to the tops of the collapsible chambers, so as to facilitate their expansion. The object of employing two collapsible chambers is, of course, to allow the filling of one chamber while the other is being emptied. O are valves arranged one in the base of each collapsible chamber, and which are adapted to allow the admission of air into the latter when extended. Each valve is connected by a chain to the top of the chamber, so as to be positively lifted when the chamber has been extended to a given point.

GAS-LAMPS.—Fletcher, T., and Clare, A., of Warrington. No. 2058; Feb. 10, 1888. [8d.]

This is the gas-lamp referred to in the JOURNAL for April 10 last, p. 637—the claim for the invention (in the words of the patentees) being for “a regenerative gas-lamp in which the whole of the air supply enters through a casing below the burner; in which the whole of the air for the upper side of the flame is derived from the hood or regenerative chamber above the burner in two streams, one of which is directed upon the root, and the other upon the body or tips of the flame; and in which the whole of the air supply for the under side of the flame is derived from the casing in two streams, one of which is directed upon the root, and the other upon the body or tips of the under side of the flame.”

The lamp consists of a burner A, preferably circular in cross section; a perforated casing B below the burner, and open at the top and bottom; a flange round the lower end of the casing, employed as a gallery for the chimney, and which prevents access of air to the flame except through the passages provided for the purpose; a perforated or reticulated chamber E mounted upon and above the burner, closed at the top and open at the bottom to the interior of the casing B; and a hood F (surrounding the perforated cylinder and the chamber E) closed at the top and open at the bottom, enclosing the air space G, and preferably having its lower portion shaped so as to form a deflector and reflector to the flame. There is an air space H between the burner and the casing B; and at a short distance below the top of the casing, there is a perforated plate or ring I through which the air can pass.

The whole of the air supply for the lamp enters by the lower end of the casing, within which the current is divided into two main portions, of which one passes directly upwards and through the openings in the chamber E into the air space G in the hood F, when it becomes heated, and from the lower end of which it issues in two separate streams to supply the upper side of the flame. The other portion of the current is also subdivided—one part of it ascending through the annular part H of the casing, to supply the root of the flame; while the other part passes through the perforations in the casing into the space between the casing and the chimney, to supply the under side of the flame. The perforated cylinder or ring K in the air space of the hood serves to divide the air supply to the upper surface of the flame, and to steady the currents.

SPIRAL FRAMED GASHOLDERS.

SIR,—On reading the report of the discussion that took place upon the paper recently read by Mr. Newbigging upon Mr. Gadd's invention for the construction of gasholders without guide-framing, it struck me that, if the order of things were reversed, several of the objections raised would be at once removed. If, instead of the spiral guides being placed in the tank, they were attached to the sides of the holder, and the rollers fixed at the top of the tank for the outer lift, and upon the cup for the inner lift, they would always be come-at-able; and, in my opinion, would tend to the better working of the holder. Admitted it would add considerably to the weight; but at the same time it would, I think, add considerably to the strength, and possibly it may be so arranged that the usual stiffening on the roller plates, usually placed on the inside, may be dispensed with, and partially meet this objection.

Sept. 7, 1888.

D. W.

GAS ANALYSIS.

SIR,—The apparatus used by Mr. William J. Hicks for the purpose of gas analysis is unquestionably interesting to chemists engaged on gas-works; more especially as, from his description, it is somewhat difficult to understand what advantage it possesses over the better class of apparatus already in general use. The colour tests of Harcourt and Greville, and the gas volumetric apparatus of Hempel and Lunge, surely give superior results as regards accuracy, speed, and simplicity. I do not wish to be considered as unduly criticizing a method giving evidence of so much ingenuity; but there are a number of points which appear to me to require explanation, and which I will endeavour to enumerate as succinctly as possible.

Is not the gas-bottle employed too large? A litre flask or bottle offers a considerable surface to the confining liquid; the runnings from the sides take some time to collect; and if not allowed to do so, cause appreciable errors in reading. These errors would be increased by the introduction of the absorbents direct into this vessel, as the solutions employed adhere much more to the sides than water, and require a longer time to collect. To facilitate this collection, the confined gas is usually kept at a slight under-pressure; but it is doubtful whether the apparatus in question would allow of this being done.

As regards the graduation of the gas-bottle, Can the constituents of a gas be determined which form collectively more than 25 per cent. of its bulk? If not, Mr. Hicks's statement that his apparatus “answers admirably for analysis of chimney or furnace gases” would seem, from the two following examples, to require some modification.

Analyses of Two Samples of Furnace Gases.

Nitrogen	60·7	..	61·1
Hydrogen	1·3	..	8·6
Carbonic oxide	28·0	..	24·3
Carbonic acid	10·0	..	6·0
	100·0		100·0

With respect to the construction of the apparatus, the gas-bottle very closely resembles that of Mr. Wanklyn; and there is an equally close resemblance between the vessel J (used to draw off water, &c.) and that employed with Bunte's burette. There are certainly three stoppers or corks in the bottle, where one would have sufficed; and the arrangement in the water-trough will be more difficult than the Hempel burette with levelling tube.

Are the connections]made of indiarubber, or of glass-tubing with ground joints. If of the latter material, the whole would be so rigid as to be in constant danger of fracture, and practically unworkable; while if of the former, the objections are stronger still, as reagents like fuming nitric acid and alkaline pyro have to be forced through. The nitric acid would attack and destroy the connections; and the pyro would render a sound joint between india-rubber and glass-tubing almost impossible.

If water must be used as the confining liquid, would it not have been better to have employed water saturated with a portion of the gas to be tested?

The reagents employed are introduced from an open burette, in spite of the fact that pyrogallic acid and cuprous chloride solutions are entirely spoiled by continued contact with air; and that some of the remaining reagents are by no means benefited by such exposure. No mention is made of any aspirator for withdrawing the injurious absorbents, by means of the suction-bottle; although suction from the mouth can hardly be advisable.

Can hydrogen and marsh gas be estimated by this process; and, if so, by what means?

The similarity between Mr. Hicks's method and Professor Wanklyn's reappears in the absorbents, &c., employed for sulphuretted hydrogen and carbonic acid—namely, for the former a standard solution of acetate of lead, with lead paper as the indicator; and for carbonic acid standard barium hydrate titrated with standard sulphuric acid.

With regard to the method of estimating ammonia, the gas to be tested is exposed to the absorbing influence of water, which constitutes perhaps the gravest objection to the whole apparatus. It at once raises a query as to whether the results by absorption ever could agree with those obtained by titration. Sulphuretted hydrogen (another very soluble gas) is subjected to still more severe treatment. It is shaken up with aqueous solutions; washed repeatedly; the washings are lost; sulphuretted hydrogen is then absorbed by acetate of lead; and it is then contended that the acetate solution contains the whole of the sulphuretted hydrogen. This determination of sulphuretted hydrogen completely spoils the remainder of the sample, which cannot be held to have any further recommendation.

Why does Mr. Hicks prefer naphtha to bromine or fuming sulphuric acid? I may as well here point out what appears to be a clerical error. The writer, after speaking of titration of sulphuric acid solution with potash, afterwards refers to ammonia as being used for titrating; leaving us in doubt as to which reagent is intended to be employed.

One more point occurs to me. It will be necessary to note the

absorption that takes place during the course of an analysis; and the apparatus will be found rather faulty in this respect. To get the gas-bottle perfectly vertical each time a fresh constituent is absorbed will be very difficult; for, unlike the Hempel burette, it has no accurate base to stand upon, and the slightest variation in the level would cause considerable deviation from the true reading.

As regards the corrections given for temperature and pressure, they answer well enough for results obtained by titration; but the majority of the various gases would have to be estimated by noting the absorption. The correction of the percentages thus obtained would be rather erroneous if carried out as directed in Mr. Hicks's paper. Both the bulk of the gas used and the results obtained by absorption have to be reduced to the normal state; and the percentages then calculated from the corrected results. Where the conditions of temperature and pressure are fairly constant, or where the analysis is rapidly performed, correction is hardly necessary.

Commercial Gas-Works, Stepney,
Sept. 7, 1888.

E. W. WHIELDON.

WALKER'S PATENT TAR-SPRAYER BURNER.

SIR,—In your issue of the 7th ult. a report is given of the paper read at the recent meeting of the North British Association of Gas Managers by Mr. John McCrae, of Dundee, on "Coal Tar as Fuel for Steam-Boilers." A diagram is also given of Messrs. C. and W. Walker's patent tar-sprayer burner, which is only supplied by that firm.

Now, I do not know upon what Messrs. C. and W. Walker found their claim to a patent for this tar injector or sprayer, or whatever it may be called, because for the past two-and-a-half years I have had one in use exactly like it in principle.

On Feb. 16, 1886, Mr. John Smith, of Bangor, described in the JOURNAL an injector for burning tar. I immediately made one on the same lines; and added a small needle valve (moved in and out by a screw) for regulating the flow of tar to the fire. A description of this is given in the JOURNAL dated April 13, 1886. It is a very simple arrangement (can be made by an ordinary smith for half-a-crown), and it answers the purpose admirably. Messrs. Walker's patent tar-sprayer is precisely the same idea described by Mr. Smith and myself in 1886; but made in a more elaborate form, and consequently more expensive. This is its only claim to superiority; but it does not include invention.

Gas Works, Bodmin, Sept. 8, 1888.

JAS. THOMAS.

THE SUPPLY OF OIL GAS AT COLINSBURGH.

SIR,—Referring to an article on page 427 in your issue of this week, I (in common doubtless with many of your readers whose "recollection" it is intended to refresh) feel interested in the use of mineral oil, as employed in the manufacture of illuminating gas, and especially so, when used as an enricher of poor coal gas in localities distant from rich shale, and cannel coal fields.

Naturally one might expect that the subject of oil gas production would command that breadth of view for which as a public journalist your pages are read and appreciated. You will therefore excuse the liberty I take in calling attention to the article in question, and to the somewhat prejudiced method employed in dealing with the report of Mr. Dawson, the Secretary of the Colinsburgh Gaslight Company. I do so all the more frankly because I observe that one of your contemporaries has also gone wrong, and devoted a semi-leading article of adverse criticism of the reported results, without, also (as in your JOURNAL) advancing a single argument in support of the disparaging tone adopted. On public grounds I respectfully demur to such treatment of a matter destined to perpetuate the manufacture of high illuminating power gas, by continuing a demand for it, and such as will prove a powerful factor in deservedly maintaining purity and high-power illumination, even though it should increase the price of mineral oil that at present competes so successfully with coal gas because of its low price and its convenient supply. However, as electricity was viewed in much the same way until it proved itself (as it now undoubtedly is) a formidable displacer of coal gas, it would be idle to do more than I have now ventured to do—namely, to question the propriety of disparaging that aid to the gas industry which mineral oil, whether used alone or in conjunction with gas from low quality coal, undoubtedly is.

As I happen to know that the statement given by Mr. Dawson is logically, and for all practical purposes accurate, and worthy of fair and square consideration, I would ask, in the interests of gas consumers that it be dealt with accordingly. In conclusion, I would say that 14 per cent. cannot be considered excessive "leakage," when there are over 50 gas-works in Scotland with balance-sheets recording 14 to 30 per cent. "unaccounted-for gas;" and as regards "smokiness," the correspondent "Colinsburgh," whose letter you quote from, has evidently not tried a No. 0 or a No. 1 Bray's burner with the Colinsburgh gas, as I have done, or he would have found the light about as near perfection as he is ever likely to see in this world.

Sept. 7, 1888.

"UTILITY."

[In regard to the above letter, we would point out to "Utility" and other readers specially interested in the question on which he writes, that the news "article" to which he refers was, as clearly stated last week, merely an abstract of correspondence that lately appeared in one of the Scottish newspapers. There was not the slightest attempt at commenting on the various statements made; the original words of the writers being, in the main, adopted. If "Utility" will be good enough to indicate "the somewhat prejudiced method employed in dealing with the report of Mr. Dawson," we shall at once, in fairness to that gentleman, set the matter right.—ED. J. G. L.]

"OUTSIDER'S" CRITICISM OF COLONEL MAKINS AND HIS STATEMENTS.

Alluding to the letter published in last week's JOURNAL, by a correspondent who signed himself "Outsider," the *Financial News* of Saturday writes as follows:—"When the chairman of a public company has made his annual or half-yearly speech to those whose investments he handles, he is apt to think that he need not trouble his head until the time comes round for airing his eloquence again. At these gatherings

of shareholders, weak points in the presidential address often pass unnoticed; fallacies in facts and figures escape detection; and, for the most part, practical criticism is a vanishing quantity. After the meeting is over, it may be that a few discoveries are made, and one or two proprietors regret a lost opportunity of putting the chairman through his facings. Sometimes, however, thinking that comment comes better late than not at all, the unconvinced shareholder writes to the newspapers to point out in what particulars his co-proprietors have been misinformed by the spokesman of the board. This is the course which has been taken by a shareholder, though apparently by an outsider, in regard to The Gas-light and Coke Company. This gentleman describes himself as a statistic who is in the habit of scrutinizing general statements made as to financial results. He asserts that at the recent meeting over which Colonel Makins presided, and to which we made some reference at the time, the Chairman's utterances on some points were absolutely erroneous. Colonel Makins gave, among other statistics, some figures relating to the net cost of coal during the previous half year, and described the reduction which had been effected as the largest within his recollection. But the amateur statistic is down upon him with a confuting array of figures industriously worked out. It seems that the net reduction during the half year ended June 30, as compared with the corresponding period of the previous year, has been considerably exceeded in the course of the Company's past history. Nor did this occur in any remote period of that history; for Colonel Makins's critic points out that the cost of coal was lower in the half year immediately preceding the period which the Chairman was discussing, as well as in the half year ending June 30—a period to which Colonel Makins made special reference. If the statistic is right, Colonel Makins was wrong, and wrong without any justification; for no Chairman, however multifarious his parliamentary or business engagements, can be allowed to limit his recollection to a period of half-a-dozen months. It would be interesting, therefore, to know how Colonel Makins, who must have had ample means of accurate information at hand in the Company's office, could have been induced to make so misleading an assertion on a point of vital interest to those whom he addressed. Figures are sometimes troublesome; the early anguish of simple arithmetic has left its mark on most of us. Multiplication is still vexation to many; but in riper years, when the handling of figures is not compulsory, it should be required of those who elect to expound them, to learn their lessons first. If, as the amateur statistic declares, the actual and comparative results of past expenditure for coals by The Gas-light and Coke Company can be ascertained by the four elementary rules of arithmetic, how came it to pass that the Chairman went so egregiously astray? A little sum which might be worked out by the Board scholar of the period ought to be within the competency of an experienced member of Parliament and Governor of an important public Company, which deals with millions of money. There are one or two passages in the critic's letter which indicate that he is an admirer of Mr. George Livesey, Chairman of the South Metropolitan Gas Company, whose public relations with Colonel Makins are not exactly of a cordial character. But with these matters we do not concern ourselves. We have before now criticized Mr. Livesey's action, even more plainly than that of Colonel Makins, or of any other chairman. Chairmen as a class are too prone—and it is not surprising—to make the colours rosy; but their duty is to be accurate, and it is just as well that there should be a 'chiel amang' them capable of taking notes, with the view of putting on the useful drag of criticism."

SHREWSBURY GASLIGHT COMPANY.—In their report for the year ending June 30 last, the Directors of this Company state that the available balance of profit amounts to £5546 17s. 9d., out of which they recommend that the authorized dividend be declared. There has been a small increase in the consumption of gas during the year; and there is also a slight improvement in the returns for residuals. The unaccounted-for gas has been 4.38 per cent. The reserve fund now amounts to £6876, and is fully invested in 2½ per cent. Consols. The Directors have deemed it advisable to revise the prices charged for rental of meters, and have reduced the same to about one-half the amount hitherto charged.

THE GAS SUPPLY OF HEANOR.—At the meeting of the Heanor Local Board on Tuesday last, the advisability of taking steps to purchase the plant, &c., of the Langley Mill and Heanor Gas Company, Limited, was under consideration. Mr. Bowley moved, and Mr. Watson seconded—"That this Board constitute itself into a Special Committee to consider the advisability of negotiating for the purchase of the undertaking of the Langley Mill and Heanor Gas Company, Limited, and take such preliminary steps as they may deem advisable." Mr. Bowley remarked that the town was increasing in population; and the purchase of the gas-works would be a great benefit to the parish, inasmuch as the price charged for gas would be lowered considerably to the consumers, and the rate-payers would receive double benefit. The Chairman said that some four or five years ago this question came before the Board. The Gas Company were then willing to sell for £16,000; but the sum was so high that the Committee appointed could not advise the purchase. Mr. Oldershaw said the Company would require double that sum for the property now. The Chairman thought the matter should be deferred, as probably in a short time the electric light would be within easy distance. The motion, however, was carried.

GLOUCESTER GASLIGHT COMPANY.—A very favourable report was presented by the Directors at the half-yearly meeting of this Company on the 30th ult. The affairs of the Company, they stated, continued to progress satisfactorily. There was a considerable increase in the sale of gas during the half year, as compared with the corresponding period of 1887; and the revenue from residual products showed a steady improvement. The net profit for the half year, after providing for interest on mortgages, &c., was £4238 9s., out of which the usual dividends were declared. These will require £3334 18s., leaving a balance of £903 11s. to be carried forward to the next accounts. In their previous report, the Directors expressed a hope that should the business of the Company continue to progress favourably, they would be able to make some concession in the price of gas; and they announce that the result of the past half-year's working was so satisfactory that they feel justified in making a reduction in the price of gas of 2d. per 1000 cubic feet—such reduction taking effect as from the commencement of the current half year. This, when the discount for prompt payment is taken off, reduces the price to the general consumers to 2s. 5½d. per 1000 cubic feet. The price is 2s. 7d., with a discount of 5 per cent. to all consumers for prompt payment; and 10 per cent. extra to those using 1,500,000 cubic feet per annum. The Directors trust that this low price will be an inducement to a more extended use of gas for cooking and other purposes, as well as for lighting.

Miscellaneous News.

THE GAS COAL CONTRACTS OF THE HALIFAX CORPORATION.

THE CHARGES AGAINST GAS-WORKS OFFICIALS.

The Monthly Meeting of the Halifax Town Council was held last Wednesday—the Mayor (Alderman James Booth) presiding—when it was intended, at the close of the usual business, to have a meeting of the Council in Committee to take into consideration what is known locally as “the Gas Scandal.” At the instigation of the Mayor, however, the reporters were invited to remain. There had, he said, been so many garbled statements made with regard to the question they were to consider, that it would be the best and fairest way for the public to know when a clear and distinct statement was made to the Council on the subject.

The Mayor, in opening the proceedings on behalf of the Sub-Committee who had had the matter referred to them, said that the members of the Council would remember that about two months ago certain statements appeared in the *Pall Mall Gazette*, and certain letters were received, imputing certain malpractices in Halifax, and which statements reflected upon the Gas Committee of the Corporation. A Sub-Committee was appointed; and, in the first place, a resolution was passed authorizing an indemnity to be given to a Mr. T. K. Fox, so as to enable him to make charges in accordance with the letter he had written to the Corporation. It was afterwards found that this indemnity was considered too narrow; and the Council then passed a resolution giving full power to grant, on the part of the Corporation, the indemnity required. Well, during his (the Mayor's) absence, this indemnity was drawn up; but it was afterwards found that the Council had not the power to give any such indemnity. In fact, the indemnity, if given at all, must be given by the Mayor acting for the Corporation. Now, he had no objection whatever to give this indemnity—he spoke for the Committee, and his present statement must be taken as emanating from the Committee—but it struck him that there was a far simpler way by which to attain their object. By signing the indemnity, they would be putting money into the pocket of an individual, or, in other words, furnishing him with the “ways and means” to fight them; and should the charges not be sufficiently proved, they would have had to part with a considerable amount of money. Well, seeing that Mr. Carr was so directly implicated in this charge, and also knowing that he would be capable of sustaining an action against the *Pall Mall Gazette*, and also be able to prove for substantial damages, and that if they gave the indemnity to Mr. Fox they would then simply have to call on Mr. Carr to take action, the Committee thought they would be justified in asking Mr. Carr to himself take action against the *Pall Mall Gazette*. Well, when this was named to Mr. Carr, he said: “I am not prepared to spend any money over it.” He (the Mayor) replied at once that, so far as any money question was involved, if the Council would not indemnify Mr. Carr he was prepared personally to indemnify him against any loss, provided he proved that he was innocent. He assured Mr. Carr that he should not be one farthing out of pocket—that all they wanted him to do was to take action, and prove the charges to be groundless. Well, notwithstanding these explanations, Mr. Carr did not seem willing to take action. Therefore, the only alternative for the Committee was to tell Mr. Carr that he must either take action against the *Pall Mall Gazette* or send in his resignation; and this was the conclusion the Committee had come to. They must insist upon Mr. Carr taking action (holding him free from costs if he proved his innocence), or else resign his position. He therefore proposed a resolution to the effect that Mr. W. Carr be requested to commence an action for libel against the *Pall Mall Gazette* (the Council to indemnify Mr. Carr against costs); and in case of his declining to do so, that he be asked to resign his position as Gas Manager.

Alderman DAVID SMITH seconded the resolution.

Alderman MICHAEL BOOTH, in supporting it, said that, as a member of the Council, he felt a great responsibility in the matter. The public had a great deal to say on the subject; but he had all along held to the hope and belief that Mr. Carr would be able to clear himself, and he still believed he would do so at the finish. He thought the Mayor's proposition a right one.

Mr. J. W. BROADBENT also supported the motion. At the same time he was prepared to go further than this, and say that, if Mr. Carr would not take active proceedings, the Council would themselves take proceedings. If Mr. Carr resigned, was that, he asked, to be the end of the business? They might perhaps think harshly of Mr. Carr; but if he did not take action, it might be said that he could not prove his innocence. If it was a question of money with Mr. Carr, then the Mayor could not do more than he had engaged to do. Even if the action was lost on technical grounds, Mr. Carr would not be out of pocket. It was the bounden duty of Mr. Carr to take action; and it was the bounden duty of the Council to insist on his taking action or resigning.

The Mayor pointed out that when they took Counsel's opinion, they took it on the point whether or not the Corporation could take action. As far as Mr. Carr was concerned, the amount of evidence that could be brought to bear on the question proved that the article referred to Mr. Carr.

Alderman LONGBOTTOM said he had not seen the article in the *Pall Mall Gazette*; but he understood that the Town Clerk had taken Counsel's opinion as to whether or not it was actionable.

The Town Clerk read the opinion of Counsel (Mr. T. D. Wright), which has already been published; but he pointed out that at the time this opinion was taken, Mr. Carr had not made his application for the post of Gas Manager to the Nottingham Corporation, and no one could then be said to have suffered specific damage from the article. The Town Clerk then went on to say that he did not apprehend any difficulty in agreeing to the terms of their indemnity; and as soon as it was signed, Mr. Fox stipulated to give the names and addresses of the parties against whom malpractices were alleged. When the Committee met, to consider as to the signing of the indemnity, one of their number said, “Why should not Mr. Carr commence an action against the *Pall Mall Gazette*?” He (the Town Clerk) might say that the Committee had received information to this extent—namely, that three names would be mentioned against whom malpractices were alleged; and it had also been stated, in confidence, that Mr. Carr's name would be one of the three. Therefore, in insisting upon his taking action, they were not asking him to put on a cap and make it fit the statements of the *Pall Mall Gazette*. He would also point out that the reference to Mr. Carr had been morally sanctioned by the public and by newspaper comments on the subject; and he read extracts from an article in the *Journal*, in which the allegations were, he said, taken to reflect directly upon Mr. Carr. What, therefore, would be thought of Mr. Carr if he hesitated to take proceedings after the indemnity which had been offered him? He had no hesitation in saying that if Counsel's opinion had to be sought at the present stage, it would certainly be that Mr. Carr ought to take action against the *Pall Mall Gazette*.

Mr. Jessor pressed for an answer to Mr. Broadbent's question as to what steps the Council would take if Mr. Carr resigned.

The Mayor replied that the question was one which it would not be prudent to answer at the present stage; but he would assure the Council confidently that they would get to the bottom of the affair. In reply to further questions, he said that they would get the three names, whether Mr. Carr took action or not, if the resolution now before the Council were passed.

Alderman POLLARD pointed out that, even if Mr. Carr resigned, they could still give the indemnity to Mr. Fox.

Alderman MINGLEY thought it was rather hard upon Mr. Carr, seeing that there were allegations against three names, that he should be singled out and asked to take action. He was in a bad state of health; and the excitement of an action would tell adversely upon him. He had long known Mr. Carr, and had always regarded him as a very useful public servant. At the same time, the statement of the Mayor was a very fair one indeed.

The Mayor pointed out that they only had power over those who were their servants; but Mr. Carr did not urge ill-health as a reason for not taking action. He (the Mayor) announced that if the Council did not pass the resolution, he would sign the indemnity. Therefore it would make no difference in that respect to Mr. Carr.

Mr. OSBORN observed that it was stated outside that they wanted to make Mr. Carr the scapegoat.

The Mayor repudiated any such intention, and intimated that they would certainly be put in possession of the three names alluded to. He also observed that if half as much had been said about himself as had been said about some persons, he should have taken action long since.

Mr. G. CLEGG supported the motion, as in his opinion the course taken by the Committee was clearly the right one. Mr. Carr had not one iota to fear; and as to the effect upon his health, to his mind the having to bear the reflections that were cast upon him was far worse than embracing the opportunity of clearing himself before the public.

After some few further remarks by other members of the Council, the motion proposed by the Mayor was put and carried unanimously.

The Halifax Correspondent of the *Bradford Observer* (from which the report given above was prepared), writing on Thursday last, says: “The statements made at the meeting of the Halifax Town Council on Wednesday evening have produced a deep and satisfactory impression among the ratepayers. The feeling universal throughout the district is that the matter must, at any cost, be sifted to the very bottom. Acting on behalf of Mr. William Carr, Gas Manager to the Corporation, Mr. Walter Storey, solicitor, has written to the Mayor stating that Mr. Carr has decided to resign rather than fight an action which must prove abortive.” The *Halifax Courier*, of Saturday's date, however, says: “It is not true, as has been publicly stated, that the Manager of the Halifax Gas-Works has sent in his resignation.”

THE WOLVERHAMPTON CORPORATION AND THE GAS COMPANY.

At Yesterday's Meeting of the Wolverhampton Town Council, the Special Gas Committee presented the following report:—

At a special meeting of the Council, held in December last, your Committee were re-appointed to consider the question of the supply of artificial light for the use of the inhabitants of this borough, and to obtain such professional advice with reference thereto as they might think fit, and to report thereon to the Council. Your Committee deemed it desirable to submit a series of questions to various corporations and gas companies in the country, with regard to their respective gas undertakings; and a large number of replies have been received. It was also considered necessary to ascertain, as far as possible, to what extent electric light and oil were being used in those places for lighting the public streets. Your Committee have to report upon the various points as follows:—

OIL-LAMPS.

With regard to oil-lamps, your Committee find that they are used to a very limited extent only for street lighting; and they, therefore, do not propose to report to the Council the details of the information which they have obtained relative thereto. Your Committee have, however, every reason to believe that, owing to the cheapness of oil, and the greatly improved character of the lamps now in use, oil is being used for household purposes to a larger extent than formerly, and is becoming in this respect a formidable rival to gas.

ELECTRIC LIGHT.

At Eastbourne, Hastings, and Blackpool electric light is used for lighting some of the principal places, streets, and thoroughfares; but your Committee have not sufficient information from those boroughs to enable them to judge as to the relative cost of gas and electric light for the areas supplied. The Corporations of Bristol, Carlisle, and Huddersfield have obtained Provisional Orders for the supply of electric light, but they have not been acted upon; whilst at Norwich and Middlesbrough electric light has been tried and its use abandoned. The Town Council of Bath have recently decided to light about fifty streets with electric light.

Your Committee have consulted Messrs. Elwell-Parker, Limited, of Wolverhampton, with regard to the cost of lighting the streets of the borough with electricity, who cannot at present recommend the Corporation to undertake the lighting of the streets alone, owing to the length of leads necessary to be used for the purpose, and the amount of labour of laying down mains necessary for this comparatively limited amount of lighting. Messrs. Elwell-Parker are of opinion that “if Wolverhampton is lighted by electricity, it must be arranged to be done upon the same plan as gas—that is to say, by taking off the mains to light dwellings or shops, or wherever the current could be sold, so as to utilize the cables to the greatest extent.” In case of carrying out such a plan of lighting, they have no hesitation “in recommending the Corporation to use electricity, as electrical engineering is sufficiently advanced to make the thing a thorough success, and to give a good return for capital invested at reasonable rates charged. Even in small installations, where not more than 4000 lights are used, it will compare favourably with gas at 3s. 6d. per 1000 feet. If a 40,000 lamp installation were entered into, the present price of gas in Wolverhampton could be successfully competed with by electricity.”

Your Committee find, on comparing the estimate of cost of plant, &c., which they have received from Messrs. Elwell-Parker, Limited, for lighting 60 miles of streets in the borough, and for providing for the probable requirements of the inhabitants, with that of Mr. J. N. Shoolbred, which was submitted to the Council in November, 1882, and which provided for the lighting of a small area in the centre of the town only, that an enormous reduction has been made in the cost of such plant, and there is no doubt that on the further development of electric light, still greater reductions will be made.

Your Committee may also here call attention to the Electric Lighting Act, 1888 (51 and 52 Vict., c. 12), amending the Electric Lighting Act, 1882. Under this Act a Provisional Order for the supply of electric

light in the district of any local authority is not to be granted, except with the consent of the local authority, unless where such consent is refused the Board of Trade are of opinion that such consent ought to be dispensed with, when they are to make a special report, stating the grounds upon which they have dispensed with such consent. The grant of authority to any undertakers to supply electricity within an area is not to restrict or hinder the granting of a License or Provisional Order to the local authority, or to any other company or person within the same area. The Act also gives local authorities power to purchase the undertakings for the supply of electric light from the undertakers within six months after the expiration of a period of 42 years from the date of the Act confirming the Provisional Order, or the passing of the Special Act, or within six months after the expiration of every subsequent period of 10 years, or such shorter respective periods as may be specified in the Provisional Order or Special Act. These periods in the former Act were 21 and 7 years respectively. The sale is to be made without any additional price in respect of compulsory purchase or goodwill, or of any profits which may, or might have been, or be made from the undertaking, or of any similar considerations; but subject to any variation of the terms which may be made by the Board of Trade. It is generally thought that these modifications of the principal Act will have the effect of stimulating and extending the use of the electric light.

GAS.

Your Committee have obtained valuable information from 87 towns on this subject; but in attempting to make a general comparison between the price of the gas supplied in these towns and that supplied in Wolverhampton, they have met with considerable difficulty, inasmuch as not only does the price of gas vary considerably, but also the illuminating power thereof. Moreover, in some towns gas consumers get advantages from the allowance of discount for cash payments; in some a reduction is made to large consumers; whilst in others no charge is made for the hire of meters. Your Committee, however, find that in many boroughs, apparently not more favourably situated than Wolverhampton, the gas consumers are on the whole supplied to better advantage than in this borough.

Your Committee have thought fit to lay the gas accounts which have been filed with the Clerk of the Peace of this Borough, the report of Mr. Edward Carter to the County Quarter Sessions on the state and condition of the concerns of the Wolverhampton Gas Company, dated 1868, together with other necessary documents, before Messrs. Howard Smith, Slocombe, and Co., of Birmingham, who are thoroughly versed in the examination of gas accounts, for their report thereon. Their report has been submitted to the Gas Company, who have, through their Solicitors, Messrs. Manby and Son, and Messrs. Neve and Cresswell, replied to it; and such reply has been sent to Messrs. Howard Smith, Slocombe, and Co., for their remarks thereon. A copy of this latter document has also been sent to the Gas Company, from whom no further reply has been received. The chief points raised by Messrs. Howard Smith, Slocombe, and Co., are seven in number, and your Committee propose to take them seriatim.

1.—Share Capital.

Messrs. Howard Smith, Slocombe, and Co. call attention to the conversion by the Gas Company of the loan capital of £10,000 into capital bearing 10 per cent. dividend, and raise the question as to the legality of the conversion, and its effect upon the finances of the Company.

The Solicitors to the Gas Company reply that the legality of the conversion was not raised in Mr. Carter's report of 1868, nor before the Court of Quarter Sessions; that the conversion took place in 1861, under the powers of the Companies' Clauses Act, 1845, and was recognized by the Order of the Board of Trade in 1875. Under these circumstances, and owing to the lapse of time which has taken place, your Committee do not propose, unless otherwise instructed by the Council, to pursue this point further.

2.—As to the Payment by the Gas Company of the Dividends on the 10 per cent. Capital, free of Income-tax.

Messrs. Howard Smith, Slocombe, and Co. say "that, in case the practice of paying the 10 per cent. dividend free of income-tax, is illegal, there is a sum (at the present rate of the tax) of nearly £250 per annum paid to the shareholders annually, which ought to remain in the funds of the Company. If the tax had been deducted, as it should have been, during only say the last 12 years, there would have been no necessity to reduce the reserve-fund by about one-half, for the purpose of assisting the profit and loss account, as was done on the 31st of December, 1887."

The Solicitors to the Gas Company reply "that the Directors are prepared to stand on the legality of the course they have adopted in paying dividends free of income-tax; that the question was dealt with in Mr. Carter's report, and was brought before the Court of Quarter Sessions, but no opinion was then expressed by the Court which would justify the unhesitating opinion of Messrs. Howard Smith, Slocombe, and Co. in the present report."

The Town Clerk is of opinion, having regard to the decision in a case (which was not brought to the notice of the Court of Quarter Sessions at Stafford) that the practice is illegal.

3.—Capital Outlay.

Messrs. Howard Smith, Slocombe, and Co., in their report fully criticize the capital outlay made by the Gas Company, and state "that the filed accounts certainly demonstrate considerable variation in the rate of progress of the capital expenditure during the last 20½ years. They suggest 'that it may be that there has been during the first half of the period a lack of accurate discrimination between capital and revenue; but an independent answer to that question could only be obtained at the cost of an exhaustive inquiry into details.'"

In reply to this, the Solicitors to the Gas Company say "that the variation in the rate of progress of the capital expenditure during the 20 years covered by the report, must be a matter for which the Accountants must have been prepared from their examination of the accounts of other gas companies, and it is not one to cause surprise or remark. The capital outlay on works for the manufacture and supply of gas is, both as a matter of necessity and economy, unequal. Since the report of Mr. Carter, in 1868, the Board have been careful accurately to discriminate between capital and revenue."

Your Committee do not propose to enter more fully into the matter in this report, although they consider it one which should in the future receive the careful attention of the Corporation.

4.—Cost of Coal.

Messrs. Howard Smith, Slocombe, and Co. state that "they have made some calculations with a view of comparing the cost of coal at Wolverhampton with that at other places during the year 1885—that year being the last in respect of which they had before them the 'Analysis of Metropolitan, Suburban, and Provincial Gas Accounts,' prepared annually by Mr. Field; and they find that, whereas the cost of coal per 1000 cubic feet of gas sold during the year 1885 was at Wolverhampton 18-52d., the cost at Birmingham was only 11-89d.—the average cost of the nine provincial corporations analyzed by Field, was 1s. 1-70d., and the average

of the ten provincial companies analyzed was 1s. 3-14d. This apparent excess in the cost of coal at Wolverhampton is, however, doubtless due to some extent to the fact (evident upon the accounts) that coal is used there for fuel instead of coke. But, allowing for that fact, there is a balance of excessive cost apparent, which is largely counterbalanced by the better revenue from coke; this being at Wolverhampton exceptionally good. The revenue from coke per 1000 cubic feet of gas sold, at the places quoted above, is as under:—

Wolverhampton	7-00d.
Birmingham	3-02
Nine Provincial Corporations quoted by Field	2-43
Ten Provincial Companies quoted by Field	3-29

But the whole of this seeming advantage cannot be charged against Wolverhampton as compared with the other places, because assuming (as stated above) that at Wolverhampton coal is used for fuel instead of coke, all the coke made necessarily remains in hand for sale, thereby increasing the comparative revenue. Giving, however, full credit for this circumstance, it is probable that Wolverhampton gains something between 2d. and 3d. per 1000 cubic feet from the superior price obtained there for coke. This favourable realization from coke aids, of course, in neutralizing the apparently excessive cost of coal; and the following table shows what the net cost of coal amounts to, after deducting coke and all other residuals:—

Wolverhampton	7-45 d.	Per 1000 cubic feet of gas sold.
Birmingham	4-96	
Average of nine Provincial Corporations	6-26	
Average of ten Provincial Companies	7-86	

In reply, the Solicitors of the Gas Company state "that the Company have, during the period covered by the report, used coal for fuel instead of coke; and have therefore had a larger quantity of coke for sale, and the coke made has been of a superior quality. Wolverhampton seems to compare unfavourably with most of the corporations and companies named in the report, owing to a large extent of its mains and service pipes being laid in ground affected by mining operations—involving an exceptional loss by leakage; and owing to many of the districts supplied with gas being thinly populated. Birmingham and other large towns have a larger day consumption of gas, which much reduces the percentage of gas unaccounted for. The comparison instituted is based not on the gas made, but on the gas sold. The table given above, showing the net cost of coal, cannot be considered unsatisfactory; as, although the estimate is based on gas sold, it shows that the cost to Wolverhampton is 0-1d. less than the average of ten provincial companies."

In reply to the above observations, Messrs. Howard Smith, Slocombe, and Co. state "that they have no opportunity of ascertaining the quantity of gas made—the published accounts and statistics do not give the information; but if they had those figures before them, they would still have considered the gas sold, according to the plan of Field's tables, the best test of results. It is true that the net cost of coal, after deducting residuals, is at Wolverhampton less by 0-1d. per 1000 feet than the average of ten provincial companies quoted; but that, with a great deal more, is evidently due to the advantage Wolverhampton gains upon coke. Notwithstanding that advantage, however, the net cost per 1000 feet at Wolverhampton is 2-49d. per 1000 feet (equal to 50 per cent.) more than at Birmingham (7-45d. against 6-96d.), and 1-19d. per 1000 feet more than the average of the nine provincial corporations quoted (7-45d. against 6-26d.)." With regard to the suggestions made by the Solicitors to the Company, as to the leakage by mining operations, Messrs. Howard Smith, Slocombe, and Co. compare Tipton and Dudley with Wolverhampton, and point out "that the gas sold at Tipton during the year ended March 25, 1887, was equal to 9213 cubic feet per ton of coal carbonized, and the return for Dudley, year 1886, gives in the same way 8904 cubic feet per ton, against 8281 cubic feet for Wolverhampton in the year 1886." As to the sparseness of population, the Accountants point out "that it must be very considerable indeed to appreciably affect a comparison with the towns referred to in the report; and the value of the Company's suggestion on this point could only be efficiently tested in figures by a comparison of the capability for supply per head of population of the Wolverhampton mains with that of the other places named." With regard to day consumption, the Accountants say "that this cannot be tested without recourse to information which is not published, and which might be difficult to obtain. If they could ascertain the quantity passing through the station-meters at Wolverhampton and some other large companies during the hours of daylight and darkness, they would be able to ascertain how far this statement is well founded." Speaking generally, they would have thought "that an important manufacturing town like Wolverhampton would not, in this respect, compare unfavourably with other large towns; and they ask if the comparison were to the disadvantage of Wolverhampton, would it really be a matter of any great moment if the mains and service pipes were in good condition and the pressure properly regulated to the requirements?"

5.—Yield of Gas Sold Per Ton of Coal.

Messrs. Howard Smith, Slocombe, and Co. state that they find the yield of gas per ton of coal in Wolverhampton is poor, compared with that at other places. For the purposes of calculating the yield per ton (on the basis of the gas sold) they have taken the year 1886, making their comparison upon the figures given in the Board of Trade returns. The yield at Wolverhampton was only 8281 cubic feet per ton of coal carbonized, whereas the yield at Birmingham was 9305 cubic feet per ton. The average yield of all the Staffordshire companies, other than Wolverhampton (most of them small concerns), was 8297 cubic feet per ton; and the average of all the Staffordshire corporations (other than Walsall) was 9096 cubic feet per ton. They state that "they excluded Walsall from the calculation because the apparent yield there is so small that it is fair to presume some mistake has been made; possibly the fuel coal has been included as well as that carbonized." Messrs. Howard Smith, Slocombe, and Co., in concluding this important division of their report, state that "they think they have now shown that there is evidence upon the accounts tending to suggest a want of economy, or manufacturing skill, or both, in the principal item of expenditure, coal, sufficient at least to call for inquiry."

In reply, the Solicitors state "that the reason which the report gives for the exclusion of Walsall from the calculations applies in fact to Wolverhampton; fuel coal having been included, as well as that carbonized, in the quantity stated in the filed accounts for 1886. The Board repudiate the suggestion that the accounts furnish evidence of a want of economy or manufacturing skill."

Messrs. Howard Smith, Slocombe, and Co. say, with regard to this, "that the reply of the Company under this head is based upon a misconception of their report. That their calculation of the yield of gas per ton of coal carbonized was not made upon the figures of the filed accounts, which do not distinguish between coal carbonized and fuel coal; but (for Wolverhampton as well as all the other districts referred to) upon the quantities stated in the Board of Trade returns to have been carbonized—

merely altering the total of gas sold at Wolverhampton to agree with the quantity shown in the filed accounts, assuming (as now appears to have been the fact) that the filed accounts give the true total. They excluded Walsall from the Board of Trade returns, suspecting that the return in that case had inadvertently combined coal carbonized and fuel coal in one total; and having no means of resolving the doubt, their only safe way was to leave Walsall out of account altogether."

N.B.—Inquiry has been made as to the Walsall return. It is found that a mistake has been made in it, as the number of cubic feet of gas sold per ton of coal carbonized was 9023; thus adding confirmation to the before-noted calculation.

6.—Fittings.

Messrs. Howard Smith, Slocombe, and Co. state "that if the items of expenditure and income in the filed accounts described as 'fittings' relate, as they presume they do, only to the fittings' work done for and charged to consumers, that branch of the Company's business would appear to have been singularly unprofitable. There has been an apparent loss in every one of the ten years for which they have copies of the filed accounts, heaviest in the last two—the loss in 1886 and 1887 having been at the rate of more than £500 per annum. If rent, interest on capital, and proportion of management charges were added to the expenditure, the loss would be much more serious than it is. On income from fittings of only £2044 18s. 9d. in 1887, it is hardly conceivable that such a loss can have been really sustained; and it would be well to inquire whether the expenditure does not cover payments which should properly be included under some other head."

The Solicitors reply that the Company's meters are not included in this item, "as they are not treated as capital, but as part of the Company's stock. If the income and expenditure in respect of meters are added to those in respect of fittings, the result will show an annual profit of about £500, instead of a loss to that amount."

With regard to this, Messrs. Howard Smith, Slocombe, and Co. say, "they do not quite understand the reply under this head; but if the paragraph means that some portion of the expenditure in relation to meters is included under the head of fittings, it is obvious that the accounts are inaccurately stated, because in the filed accounts of each year there is a sum charged (quite apart from fittings) described as 'repairing, renewing, and refixing meters.' These charges appeared to them to be about what might be anticipated under that branch of the expenditure, and no one would expect to find a second and a heavy charge in respect of meters concealed under the head of 'fittings.'"

7.—Bad Debts.

Messrs. Howard Smith, Slocombe, and Co. report "that the charges for bad debts are heavy; about double the average cost per 1000 feet of the Metropolitan and Suburban Companies quoted in Field's book for 1885, and about four times the average of the Provincial Corporations and Companies referred to by him. The average allowances at Wolverhampton, during the ten years from 1878 to 1887, gives about £630 per annum, on a total income from all sources of less than £57,000 per annum—equal to about 1½ per cent. There does not appear to be any deposit system in operation in Wolverhampton; but, even without that, for a monopoly having power to cut off in any case of arrear, the percentage seems high."

The Solicitors to the Gas Company reply "that the charges for bad debts were a few years ago exceptionally heavy. In recent years the charges under this head have considerably diminished; and the average now shows a much less percentage than that stated in the report. The Directors are responsible to their shareholders for the financial policy of the Company; and they are satisfied that their policy with respect to bad debts and other similar questions has been dictated by prudence."

In answer to this Messrs. Howard Smith, Slocombe, and Co. say "that the reply admits that the charges under this head were some time ago exceptionally heavy, though considerably diminished in recent years." As to this qualification, they remark that "the loss by bad debts is still, so far as the filed accounts go, in excess of the general average, and considerably more than the average shown by the provincial corporations and companies quoted by Field."

General Conclusions.

Your Committee, in concluding their inquiry, desire to disclaim any suggestion of antagonism to the Gas Company in respect of the steps which they have taken. They have examined in an impartial manner the evidence brought before them; and in view of the facts of the case, they are bound to remark that the position occupied by the Gas Company, by virtue of their legal monopoly, as regards the gas consumers, cannot be accepted as satisfactory to the public.

Your Committee consider that this assertion is supported by the evidence adduced before them, which the Council will note is entirely of an official character, being based upon either the Board of Trade returns, the filed accounts of the Wolverhampton Gas Company, or direct communications from corporations or private gas undertakings. It is, of course, difficult, if not impossible, for your Committee to investigate the details of gas manufacture. They can, therefore, only concern themselves with a comparison of results; and hereby the conviction is forced upon them that the public of Wolverhampton are not so well served by the local Gas Company as the inhabitants of many other boroughs. While not prepared to express a decided opinion upon the observation that "there is evidence upon the accounts tending to suggest a want of economy or manufacturing skill, or both, in the principal item of expenditure, coal," your Committee are bound to emphasize the fact that in Wolverhampton the cost of coal (both in the gross and less residuals) per 1000 feet of gas sold is considerably in excess of Birmingham and the other provincial corporations referred to; while on the other hand, the explanation of this discrepancy offered by the Gas Company entirely fails. Again, in the examination of another very practical point—viz., the yield of gas sold per ton of coal carbonized—the Wolverhampton Gas Company appears to great disadvantage as compared with the working both of distant and local undertakings. This point is further clearly proved by the comparison of Wolverhampton with a group including Birmingham and eight Staffordshire gas undertakings, by which your Committee find that in Wolverhampton 780 cubic feet (equal to 9·42 per cent.) are sold per ton of coal carbonized less than the average sales of the group of towns examined. It is not less clearly demonstrated that the public of Wolverhampton do not enjoy the same illumination as the inhabitants of many other boroughs. Birmingham, for instance, provides 17·5 average candles tested at various parts of the borough, with gas at a price rather lower than that of Wolverhampton; whereas our local Company only provides 15 candles guaranteed, or 16·25 candles as ascertained by test. It has appeared to your Committee that it would be fair to make comparison of the number of candles of illumination provided for the price charged in other boroughs with the same calculation in Wolverhampton; and they have therefore taken twenty representative cases, in which by dividing the price per 1000 feet by the candles of illumination, they have obtained a figure representing the value per candle. This figure ranges from 1·1d.

to 1·7d.—the average of the twenty is 1·5d.; whereas the same figure in Wolverhampton stands at 1·8d., or about 20 per cent. in excess. Your Committee also find (as previously referred to) that in some other boroughs gas consumers are charged at rates variable according to the amount of gas consumed, with advantage to large consumers; that discounts for cash payments are allowed; and that meter hire is not charged. Considering that the gas consumers of Wolverhampton have a right to expect from the Gas Company at least an equal quality of gas at as low a price as that supplied in other towns, and with equal concurrent advantages, they regret to observe from the records of the Town Council that hitherto the Gas Company have not met the reasonable requests of the public represented by the Corporation as your Committee think they should have done.

But your Committee feel strongly that the period has now arrived when, in common with all other commercial undertakings, the Gas Company should recognize the necessities of the times, and so far reorganize, if needful, the details of their business, as to give the public such concessions as are possible without invading the profits upon their capital which the proprietors naturally expect. Your Committee are strongly convinced that both these ends can be attained; for they have entirely failed to discover that there is, either in the situation or the circumstances of the Wolverhampton Gas Company, anything to place the Company in a more disadvantageous position than any of their neighbours.

Your Committee also think it desirable to direct the special attention of the Council to the opinion of the Town Clerk as to the illegality of the payment by the Gas Company of the 10 per cent. dividend *plus* income-tax, and also to the remarks made by the Accountants under the head of "fittings." They consider, as to the latter point, that the explanation of the Gas Company is very unsatisfactory. Referring to the filed accounts of the Gas Company for the year ended Dec. 31, 1887, your Committee find that the expenditure under the head of "fittings," amounts to £2567 9s. 1d., while the income from the same department is only shown to be £2044 18s. 9d.—leaving a deficiency of £522 10s. 4d.; and your Committee fail to see that the reference by the Gas Company to the profit made in their meter account is in any respect a sufficient explanation of this loss.

Your Committee therefore recommend to the Council that a deputation should meet the Directors of the Gas Company, and endeavour to obtain concessions upon the following points:—

1. Reduction in the price of gas, with rates adapted to the quantity consumed.
2. The allowance of discount for all monthly cash payments.
3. The abolition of charges for hire of meters.
4. Cessation of payment of dividends to shareholders on the 10 per cent. capital *plus* income-tax.

Your Committee also recommend that the Corporation should carefully examine each year the gas accounts filed with the Clerk of the Peace, in order to ascertain whether there are any special features in it to which the attention of the Council should be called; and should also make arrangements for periodically testing the gas, both as to illuminating power and purity, in various parts of the borough.

SUNDERLAND GAS COMPANY.

The Annual Meeting of this Company was held last Wednesday—Mr. E. C. ROBSON in the chair.

The CHAIRMAN, in proposing the adoption of the report and accounts (a notice of which appeared in the JOURNAL last week, p. 431), said that the central fact in the report was that they were still paying a 10 per cent. dividend. They not only did that, but they had added something to the reserve fund, which they would see, was a very respectable one. They had a balance left of £10,000, which was exceedingly satisfactory, and the result of many years' savings. They would probably infringe upon that this year, by making a considerable addition to their works in the purifying department. They purposed spending about £4000 in the erection of four new purifiers. When this was done, they would defy comparison with any gas plant in the kingdom. Their capital remained the same; but he would like to draw attention to the difference between this year and ten years ago, in order that they might see at a glance the progress of the Company. In 1878, their revenue from gas was £43,065; whilst in the year just expired the amount was £44,920. In the past year, however, they had made half as much more gas than they did ten years ago. The difference had not gone into the pockets of the shareholders, but into the public purse; and if the quantity of gas made this year had been sold at the price which prevailed in 1878, their revenue would have come to £25,000 more. With regard to reductions, they had several times—be thought three times—reduced the price of gas to the general consumer without being asked. The Directors had gone very carefully into the state of the accounts and their revenue; and they were going to lay before the shareholders a table of reductions in the price, to come into operation on Oct. 1 next. At present they invoiced the gas at 2s. 6d., and gave a discount; and they now proposed to invoice it at 2s., and give a smaller discount than before. This would reduce the price to the small consumers from 2s. to 1s. 11d. Above 50,000 cubic feet, the price would be 1s. 10d., subject to 1d. discount, or 1s. 9d. net. Above 200,000 and under 500,000 feet, the price would be 1s. 8d., subject to 1d. discount. The price to very large consumers—those of over 800,000 feet—would be 1s. 6d. net only. He believed with these prices they would defy comparison with any gas concern in the country. They had carefully gone into the matter, and saw that they were no less likely to maintain their income. The public, who would save £2200, would appreciate the reduction; and he was not without hope that they would be more than recouped by the increase in the use of gas.

Mr. STOKOE seconded the motion.

Mr. RICHARDSON, referring to the electric light, remarked that since the light had been introduced into Barnet, the shares of the local Gas Company had gone up 45.

The motion was carried.

The usual complimentary votes having been passed, the proceedings terminated.

THE GAS SUPPLY OF BLACKPOOL.—Consequent on the popularity of Blackpool as a seaside resort for residents in the Manchester and Liverpool districts, the usual order of things in regard to gas supply is largely reversed here; and an abnormal consumption of gas takes place during the month of August. Mr. John Chew, the Engineer and Manager of the gas-works, reported at last Tuesday's meeting of the Town Council that, on Bank Holiday (Aug. 6), the town was in danger of being in total darkness on account of the large consumption of gas. On Bank Holiday, 1887, night and day there was consumed 499,000 cubic feet, as against 557,000 cubic feet this year. On Aug. 20, 1887, 540,000 feet were consumed, against 580,000 feet in 1888. For the four days Aug. 20 to 23, 1887, the consumption amounted to 2,196,000 feet; and for the same period in 1888, the demand had jumped up to 2,272,000 feet—showing an increase of nearly 100,000 cubic feet in the four days. It was probable that in a very short time they would have to enlarge their works.

THE SALFORD CORPORATION AND THE COST OF THE HUNTER TRIAL.

At last Wednesday's Meeting of the Salford Town Council, a report was submitted by the Consulting Committee, who had had the matter in hand with respect to the legal charges incurred in connection with the prosecution of Samuel Hunter, the late Gas Engineer, and the civil proceedings arising therefrom. It showed that the total expense incurred amounted to £2083 12s. 6d., made up as follows:—"Criminal proceedings against Samuel Hunter: Counsel's fees, £920 8s. 6d.; travelling expenses and personal allowances of members of the Committee and officials, £266 0s. 6d.; witnesses and other expenses in obtaining evidence, £220; agency costs (on account), £200; law stationery and extra clerks' assistance, £115 15s. 6d.; Solicitor's charges, £46 3s. 8d.; shorthand notes, £47 8s. 4d.; petty cash disbursements, £58 17s. 11d.—total, £1875 7s. 2d. Civil proceedings in the case of the Corporation of Salford v. Hunter and Hawkins: Counsels' fees, shorthand notes, travelling expenses, and petty cash disbursements, £208 5s. 4d. Grand total, £2083 12s. 6d." The Committee further stated that the accounts in Regina v. Hunter are now in the hands of the agents for the prosecution, with a view to taxation as early as practicable. After this has been done, the certified costs of the prosecution will be repaid by the county; and the additional costs incurred by reason of the trial taking place at the Central Criminal Court instead of at Lancaster will be borne by Samuel Hunter. The Committee asked for the authority of the Council to direct the General Finance Committee to pay the accounts in the first instance, as well as the sum of £43 14s. 7d., the cost of defending an action brought against the Corporation by Samuel Hayward and dismissed, and which action arose out of the proceedings of the Gas-Works Investigation Committee.

The Mayor said the Consulting Committee had now ended their labours; but they were not in a position to sign any order for the payment of money. They expected to recover £400 or £500 from the county. He moved that the accounts be transmitted to the General Finance Committee for examination and payment.

Alderman WALMSLEY seconded the motion.

Alderman HUSBAND suggested that these were charges which ought to be cast upon the Gas Committee. It would be a misfortune if they were made a direct charge upon the rates.

The Mayor said, in the case of the Investigation Committee, the Finance Committee paid all the charges out of their funds; but if it were now decided that these legal expenses were chargeable to the Gas Committee, he presumed that whatever sum was recovered from Hunter would be handed over to that Committee.

Mr. JENKINSON asked whether it was true that Hunter's Solicitors had offered £20,000 to the Corporation, and that the offer was refused. It was, he said, so reported outside.

The Mayor said that while the civil proceedings against Hunter were pending, they could not discuss what offer was made, or whether one was made at all.

Alderman HUSBAND said the Consulting Committee were bound over to secrecy, and could not divulge anything that took place.

Mr. JENKINSON (to the Mayor): Do you rule that an answer, yea, or nay, cannot be given to the question whether £20,000 was offered and refused?

Mr. MANDLEY thought that before the Council were asked to vote for the resolution, they ought to have heard something about the nature of the expenses incurred, and something with respect to the progress that had been made with the civil action. It was rather too bad that those who were deeply interested in the matter should be kept so completely in the dark. He moved as an amendment—"That before sanctioning the payment of the accounts incurred in the civil and criminal proceedings against Samuel Hunter, the Council are of opinion that they should be furnished with a statement showing in detail the whole of the charges, expenses, and gifts relating, directly or indirectly, to the said proceedings; and also of those connected with the criminal proceedings against Mr. Ellis Lever; and they hereby order the Borough Treasurer to prepare such statement forthwith." He said that, although he was elected to the Consulting Committee, for some occult reason he and Mr. Rycroft were removed from it by the direct action of one member of the Committee. He was elected to the Council for the sole purpose of bringing to light the frauds going on in the gas-works; and he was determined to leave the Council the moment his work was finished. Although he had studied the question thoroughly, he was put off the Committee; and those who had systematically and with the greatest obstinacy and persistence white-washed everything that was done by the late Gas Committee and by Mr. Hunter were left on. He wanted to know what was the state of the proceedings against the men who had systematically tampered with the officials.

The Mayor: That is not the question before us. I must ask you to confine yourself to the resolution or to your amendment.

Mr. MANDLEY: Are we to pay all these expenses and not know what they are for?

The Mayor said the criminal action against Hunter was now over. In connection with it certain expenditure had been incurred; and the items were open to the inspection of members of the Council. The Council were asked to allow the Finance Committee to peruse the accounts; and if they found them correct, to pay them. That was the whole matter before the Council; and he could not allow them to go discursively into matters relating to things that occurred years ago, and that were not pertinent to the present issue.

Mr. MANDLEY: Do any of these expenses relate to any of the proceedings against contractors that are going on in the High Court of Justice?

The Mayor: We have no proceedings against contractors at present.

Mr. MANDLEY: What becomes of our statement of claim against the people who have systematically bribed our servants?

The Mayor: That is in connection with the civil action which is now proceeding. During the long vacation nothing can be done.

Mr. MANDLEY: Does this account cover any of the expenses incurred in the High Court of Justice in our proceedings against these other people.

The Mayor: About £200, I fancy.

Alderman ROBINSON said that none of the contractors had as yet been proceeded against in a civil court.

The amendment was not seconded.

Alderman WALMSLEY said that he did not remember accounts being presented to the Council under similar circumstances on any previous occasion. There was a supposed Committee before whom the accounts were presented; but they did not feel in a position to take upon themselves the responsibility of signing any document involving the payment of money. The accounts were then presented to the General Finance Committee, who returned them to the Consulting Committee. That Committee were still unmindful to undertake the responsibility of passing accounts, as to which there was some doubt; and that they felt the only thing to be done was to refer it to the Council. Mr. MANDLEY was quite mistaken in saying that any steps were taken in order to prevent himself and Mr. Rycroft having any part in the proceedings of the Consulting Committee. The Investigation Committee concluded their business, and

made their report. At a subsequent meeting of the Council, it was proposed that four gentlemen should be appointed with whom the Town Clerk might consult with regard to the proceedings then being taken against the Gas Engineer. It was agreed by the Council at the time that these gentlemen should not be called a "Committee," because Committees were bound to report to the Council and to answer questions put at the Council meetings; and it was felt that it was not desirable that statements should be made at Council meetings with respect to a criminal case that was pending. The accounts that had been presented spoke for themselves; and the Consulting Committee were satisfied that the amount would have to be paid, and ought to be paid. With regard to the proceedings against certain contractors, it would be most inexpedient at this stage to lay completely before the public what was going on.

Alderman McKERROW said it was a gross perversion of the truth to represent the matter as Mr. MANDLEY had done. Mr. Hunter would not have been apprehended and convicted had the original Investigation Committee continued to exist. It was necessary that some of the members should be removed from it.

Mr. MANDLEY (excitedly): I challenge that statement; I would have had him arrested myself.

Alderman BOWES moved, as an amendment, that the accounts be referred to the Gas Committee.

Mr. HUSBAND seconded the amendment.

Mr. RYCROFT said these expenses had been incurred, not by the Committee, but by the late Town Clerk. It was a perfect scandal that in a prosecution in which there was no legal difficulty, such a monstrous sum as £920 should be paid in fees to Counsel. As to the civil proceedings, he had learned that a writ and statement of claim had already been issued.

The Mayor: I object to these remarks; and I shall rule out of order anything you say about the civil proceedings against Hunter.

Mr. RYCROFT: It is proposed to relegate these accounts to the Finance Committee to pass them. What materials will that Committee have on which to judge as to the correctness of the charges. On April 12, 1888, £20,000 was offered—

The Mayor: This is very improper. I must call the attention of the Council to it; and they must support me in my position as Mayor, or I shall put in force rule 14.

Mr. RYCROFT: It is a most extraordinary thing that we, as members of the Council, discussing our affairs, cannot give information. We have had some extraordinary rulings in this Council Chamber; and it is a matter of surprise to me that members should sit down and be told, when they are asking questions about their own affairs, they are out of order. The members of the Council are entitled to know about their own affairs.

Mr. MANDLEY: Not in Salford.

Mr. RYCROFT: If such an offer had been made to the Consulting Committee, I should have thought it was the duty of the Committee to have called a meeting of the General Purposes Committee to consider the matter.

The Mayor: That is not the question before the Council; and as the affair is now *sub judice*, you must know you ought not to speak about it.

The amendment was then put to the meeting and rejected, and the original resolution was carried.

PROPOSED EXTENSION OF THE BURNLEY GAS-WORKS.

At the Monthly Meeting of the Burnley Town Council last Wednesday, Alderman Greenwood, in moving the adoption of the minutes of the Gas Committee, drew attention to the resolution asking for additional powers to borrow £30,000 for the extension of the gas-works. He stated that in May, 1884, Mr. S. P. Leather, the Gas Engineer, reported strongly on the importance of taking in hand the question of extending the works; and again in 1887 he spoke of the necessity of such a step being taken. The result was that Mr. Woodall was called in to report upon the whole matter. Mr. Woodall's report stated that the demand for gas in the last ten years had doubled; while the population of the town had doubled every twenty years since the commencement of the present century. The consumption of gas had thus increased at exactly double the ratio of the increase of the population; and he recommended extensions to the gas-works which would involve an expenditure of £30,000. The Committee recommended the pulling down of old buildings near the present works for the proposed extension, and had secured 7909 yards of land, or thereabouts, at 7s. 6d. per yard, for the purpose. The Committee had found, however, that they could not erect works there without—in compliance with a Standing Order of the House of Commons—giving notice to the owners of property within 300 yards of the proposed new works, and he (Alderman Greenwood) believed securing their consent. Consequently, they could not proceed with the extension until they obtained the requisite sanction from Parliament. In concluding, he submitted the following tabulated statement as to the development of the gas-works:—

	1885.	1888.	Increase.	Increase Per Cent.
Gasholder space	310,000	2,292,000	1,982,000	640
Consumption per year . .	35,540,000	296,096,000	260,556,000	733
Largest daily consumption .	2,77,000	2,009,000	1,742,000	652
Smallest " " " " " "	25,000	231,000	206,000	824
Gas meters	1,608	11,351	9,743	606
Cost of works	£31,299	£171,637	£140,338	£448
Debt on works	£31,299	£104,566	£73,257	£234
Do. per 1000 c. ft. consumed	17s. 7d.	10s. 7d.*	—	—
Population	24,000	80,000	56,000	233
Rateable value	£41,681	£244,000	£179,319	£400
Cost of works per £10,000 rateable value	£7,005	£4,750	£2,255*	£32
Cost of proposed extensions	—	£30,000	—	—
Annual charge 3½ per cent.	—	£1,631	—	—

* Decrease. Land purchased from Canal Company (7909 yards at 7s. 9d.), £3067. The minutes of the Committee were confirmed after a brief discussion.

THREATENED STRIKE OF GAS STOKERS.—A strike of the whole of the gas stokers in the employ of the Bolton Corporation (about 140 in number) has just been averted. Some time ago, Mr. Smith, the Manager, suggested to the Gas Committee of the Town Council certain alterations in the working of the carbonizing departments at their respective works, which were accepted, but with considerable modifications, however. By the new arrangement the stokers were to work twelve-hour shifts, instead of eight, as previously; and carbonize 4 tons 4 cwt. of coal, instead of 2 tons 2 cwt. The rate of wages was to be as before, 5s. for the shift. As compensation for the extra four hours' labour, and the double quantity of coal to be lifted, it was proposed to relieve the stokers from carrying the coal from the yard into the retort-houses and also wheeling out the coke. The men refused to accept the new conditions, and gave notice last week to cease work in seven days. The Gas Committee held a special meeting last Tuesday, and practically gave way to the men's demands, and subsequently the men withdrew their notices. The men, therefore, continue to work virtually as before.

NOTTINGHAM CORPORATION GAS SUPPLY.

THE STATISTICS OF THE GAS UNDERTAKING FOR THE PAST YEAR.

At the Meeting of the Nottingham Town Council on Monday last week—the MAYOR (Alderman Turney) presiding—the accounts of the gas undertaking for the year ending March 25 last, with the report of the Gas Committee, were presented.

The Gas Committee, in the course of their report, stated that the increase of gas consumption during the past year was the smallest of which they had record; being only 1·03 per cent. This, they say, mainly arises from the number of empty houses; due, no doubt, to the present condition of trade. It was, however, very satisfactory to have to report that the profit on the year exceeded by £7509 that of the previous year. The quantity of gas made was 1,405,149,000 cubic feet, against 1,383,267,000 cubic feet last year; being an increase of 21,882,000 cubic feet. This was accomplished by the consumption of 3517 tons of coal less than last year; resulting in a great saving of labour and wear though of course there was a less production of coke and residuals. The market for coke and other residuals, the Committee asserts, is somewhat looking up; so that better prices may be hoped for in the future. The profit on the chemical works for the year, after charging thereto the residuals at the current market price, and £1000 per annum rent, was £7467. Some outlay is at present going on at these works for facilitating operations there. The Committee report that they have not paid over to the credit of the general district rate any moneys in accordance with the resolution of the Town Council passed at a meeting held on June 13, 1887.* They anticipated that they would be enabled this year to hand over to the Council a much larger sum from the profits of the gas undertaking than last year; and the result being so, they have arranged with the Finance Committee that they should receive out of profits the sum of £16,000 (the same amount as last year) towards the current rate, and should receive the further sum of £7500 out of profits on account of moneys payable under the above resolution—the balance (£2500), if necessary, to be paid by the Gas Committee during the current year out of the reserve fund interest. The Committee also allude to the appointment of Mr. W. R. Chester, of Manchester, in succession to Mr. Lewis T. Wright, as the Engineer and Manager of the undertaking. Mr. Chester, they remark, is 34 years of age, and has followed the profession of gas engineering for the last 18 years. He received his early training at the Vauxhall works of the Phoenix Gas Company. He has been eight years under the Gas Committee of the Manchester Corporation; and during the last three years, has had charge of their extensive new works at the Bradford Road Station. At the close of their report was the following comparative statement of the gas and meter rental for the past two years:—

Year ending	Due	Due	Due	Due	Total
March 25.	June 25.	Sept. 25.	Dec. 25.	March 25.	
1887.	£25,949	£22,637	£52,012	£53,571	£154,171
1888.	26,550	23,070	52,644	53,572	155,837

Accompanying the report of the Committee was one presented to them by their late General Manager (Mr. Lewis T. Wright, F.C.S.), on the works and manufacturing operations during the year. It was as follows:—

Gentlemen,—The increase in the gas consumption during the year ending March 25, 1888, has been very slight indeed, yet the improved gas manufacturing arrangements which have been introduced within the last five years have borne full fruit this year; so much so that the increased consumption—viz., 1·03 per cent.—of gas has been effected with a reduction of expenditure of £1031. The following table will show the relation between the total expenditure on revenue account and gas sold during the last few years:—

Year.	£	Gas sold.
1882	121,325	1,040,665,300
1883	9 months' report only	
1884	127,831	1,163,225,500
1885	130,614	1,213,259,700
1886	124,258	1,258,405,500
1887	123,832	1,299,750,700
1888	122,801	1,313,165,800

It will be seen, whilst the gas undertaking has been growing year by year, that since 1885 each year's expenditure on revenue account has been less than that of the preceding year, and that now in 1888 the total expenditure is very little more than it was in 1882, though the gas sold has increased since then by over 26 per cent. The progressive efficiency of your works during this period has only been obtained by vigorous efforts on the part of all members of your staff; and I hope you will be able to find a way of recognizing these services.

I am glad to be able to report that the carbonizing plant is in an efficient state. During the year ending March 25, 1888, the production of gas per ton has been 10,528 cubic feet, against 10,097 cubic feet in the previous year. It is by means of this increased utilization of the gas-making constituents of the coal that the increased consumption of gas, of 13,406,100 cubic feet, has been met with the decreased consumption of 3517 tons of coal. The illuminating power has been well maintained, and averaged 18·77 candles in George Street, against 18·43 candles in the previous year. The gas unaccounted for still remains at a figure—viz., 6·55 per cent. of the gas made—which is very favourable for a gas district of such area and character as yours.

During the year there was an improvement in the market prices of some of the tar products, which have yielded £4932 more than the year ending March 25, 1887. Sulphate of ammonia being slightly better, accounts for an increased revenue of £718. Coke, which was certainly a drug a year ago, is now scarce, and better prices are being obtained.

The number of retorts at the three gas-works are: Easteroft, 424; Radford, 378; and Basford, 896; total, 1698—equal to a production of over 9½ millions per diem. This large producing power of the works is due to the increased efficiency of the carbonizing plant; a production of 5500 cubic feet per diem per retort being now easily obtained from retorts of the same dimensions that a few years ago produced but 4600 cubic feet.

The total mileage of mains of all sizes is now 259·28; there having been 2·99 miles added to the canalization during the year. The number of meters fixed on March 25, 1888 (including 251 lamp meters), was 39,597; being a decrease on the previous year of 385 meters. Of these 37,562 belong to the Gas Department, and 1735 to the consumers. The orders and calls for attention of various kinds from consumers was 41,317, against 41,104 in the previous year. There were 1546 new gas-services laid, against 1805 in the previous year.

In February last it was estimated that there were in use in the gas district the following gas-stoves:—Gas-ovens, 1071; gas-fires, 1739; small boiling-stoves, 6562—total, 9372. Of the 1071 gas-ovens, 700 were rented from the Corporation. These gas appliances form an important element in the use of gas.

In regard to the Giltbrook Chemical Works, with plant of such a nature as is used in these works, and submitted during the autumn, winter, and spring to a heavy strain, working continuously night and day, the wear and tear is very appreciable. The steam-boilers this summer are being re-fueled; and all the plant is being overhauled and repaired for the next

season. The improvements ordered by the Committee in connection with the traffic approaches to the works will no doubt prove of much service.

The following analyses accompany Mr. Wright's report:—

Analyses of Accounts for the Years ending March 25, 1887 and 1888.

	1888.			1887.

Alderman BARBER, in moving the adoption of the Gas Committee's report, said he thought the report must commend itself to the Council as being highly satisfactory. The Committee had very much to regret the small increased consumption of gas during the year; the increase amounting only to 1 per cent.—the smallest which had ever had to be recorded. This, however, was no fault of the Gas Department. They regretted to say that it arose from the bad state of trade in the town. He thought that the figures contained in the report were sufficiently clear as to render it unnecessary for him to occupy the time of the Council at any length in going into details. He had, however, prepared a short summary of the results of the working of the gas undertaking, which he would read. In the year ending March 25 last, they paid £2799 less for coal, £311 less for purifying, £738 less for salaries, and £482 less for wages. There was an increase on repairs to the works of £2125. This left a lessened expenditure on the department of £2205. In the distribution department they had paid £129 more for salaries, £1045 less for repairs, and £1946 more for meters and stoves. During the previous year, however, the contract for meters was very low; and the increased expenditure in this department was £1035. They had paid £190 more for rates, and £243 less for general management. On the expenditure side of the account, they had therefore a total of £1440 more on the one hand, and £2471 less on the other; leaving a reduced expenditure altogether of £1031. On the other side, they had received £2011 more for gas, and £334 less for public lighting. They had obtained £12 less for meter-rents, and £191 more for the rent of stoves; thus making the increased receipts £1856. During the year they had received £1112 less for coke; and there was a very remarkable thing about this to which he wished to draw their attention. During the period mentioned the gas companies in England were "rucked" up with coke. They lowered the price of their coke very much; and their stock was large. Since March 25 the Committee had been enabled to get from 1s. to 1s. 3d. more for coke. They had not a ton of coke unsold; and throughout England whole mountains of coke had disappeared. Although this might not show an improved state of trade in Nottingham, he could not but think that the great consumption of coke that had suddenly arisen must indicate a better state of trade throughout the country. During the year the Committee had received £4932 more for tar, £717 more for liquor, and £469 more for oxide and lime; making the increased receipts under this head £5006. They had received £432 less for meters and materials for distribution; and £22 less for rents. The total, therefore, of increased receipts was £6478; and added to this, they had a diminished expenditure of £1031—leaving an increased profit of £7509. There were 400 less meters fixed than in the previous year. They might be interested to know that the capital of the Gas Committee now stood at £28 per million feet of gas made less than it did at the time the concern was taken over from the Company, notwithstanding the expenditure of between £100,000 and £200,000 some years ago on the new retort-house and gasholders at Basford and the enlargement of the Radford works.

Mr. FITZGIBB seconded the motion.

Alderman GILPIN observed that the report was very satisfactory to the Council; and the Committee might be congratulated on the result of their working during the past year. He would like to ask if the use of cooking-stoves had been in accordance with the expectations the Committee previously entertained.

Alderman BARBER replied in the affirmative. They had endeavoured to

* See JOURNAL, Vol. XLIX., p. 1133.

avoid putting themselves in competition with the ironmongers of the town. The steps they had adopted had drawn public attention to the use of cooking by gas; and he was informed that ironmongers in the town had had a very large increased sale of gas-stoves in consequence of the movement. They themselves, too, had a very good trade in stoves.

Mr. FROGGATT inquired if any reduction was made for depreciation. He did not see any depreciation charge in the report, which, however, mentioned that the depreciation for repairs was £1704.

Alderman BARBER said the Committee had no fund to provide for depreciation, except at Giltbrook. The reason they had that fund was because a certain class of work was done there which they could not have repaired. To show that there was no need for a depreciation fund, they never spent less than £20,000 a year in keeping up the works to their standard point. This year they had expended altogether £26,000. They did not need a depreciation fund, therefore; because their works were better at the end of the year than at the beginning.

The report was adopted.

SALFORD CORPORATION GAS SUPPLY. THE PAST YEAR'S WORKING.

In last Tuesday's JOURNAL (p. 428), we gave a few extracts from the report of the Salford Corporation Gas Committee for the year ending March 25; and to-day we give some further particulars gathered from the report, as well as the appendix to it—prepared by the Engineer and Manager, Mr. S. Y. Shoubridge.

The make of gas increased during the last financial year by 6,532,000 cubic feet over the corresponding previous twelve months; the figures being 842,777,000 and 836,245,000 feet respectively. The leakage was, however, during the same time reduced from 50,080,800 to 46,566,600 feet, or a decrease of 7.01 per cent. The average illuminating power of the gas at all the stations (as tested by Mr. Francis Jones, F.R.S.E.) was equal to 19.76 standard sperm candles; being fractionally higher (about one-third of a candle) than was returned for the previous year. The total gas and meter rental was £127,703—composed of private consumers, £113,476; public lamps, £11,000; meter-rents, £3227. The total for the preceding year being £125,838, an increase is shown of £1865. There were 28,437 consumers supplied with gas by the Corporation, and 6828 public lamps. During the year 2052 yards of new mains were laid, and 1225 yards of new mains to replace others of less dimensions. The length of street mains in use in the borough and out-districts on March 25 last was, therefore, 376,164 yards, or nearly 213½ miles. The amount of coal and cannel carbonized during the year was: Coal, 49,601 tons; cannel, 34,264 tons—showing a proportion of 59.15 and 40.85 per cent. The average yield of gas per ton of the mixture was 10,049 cubic feet. The gas used on the works and in the offices was 11,549,000 cubic feet (1.37 per cent. of the gas made), as against 14,523,000 cubic feet (1.74 per cent.) for the previous year. The loss by leakage decreased from 5.99 per cent. in 1886-7, to 5.53 per cent. in 1887-8.

The abstract of accounts accompanying the Committee's report shows that the total capital expenditure to March 25 last was reckoned as £548,881, divided into—land acquired, £23,945; buildings and manufacturing and storage plant, £319,620; main and service pipes and works connected with same £166,855; meters, £38,461. As stated above, the gas and meter rental realized £127,703; and the revenue account shows that residuals and a small amount (£190) from rents raised the total income to £145,809. Coke brought in a net amount—allowing £511 for yard labour—of £7537; tar, £4070; and ammoniacal liquor, £6273. A sum of £61,525 was carried to the credit of the profit and loss account; the expenditure on revenue account being £84,284, made up as follows:—

Manufacture of gas—			
Coals, including labour, carriage, and all expenses of depositing on works . . .	£46,610	2	7
Carbonization—wages of stokers and foremen . . .	11,050	11	3
Purification—wages and materials . . .	1,471	4	5
Salaries of Superintendents and Analysts . . .	666	18	0
Repairs of works and plant . . .	9,060	15	8
	£68,859	6	11
Distribution of gas—

Bad debts—			
Amount written off . . .	£1,148	17	5
Less balance of bad debt fund . . .	982	9	2
	166	8	3
	£84,284	9	11

The report and accounts above referred to were presented to the ordinary monthly meeting of the Salford Town Council last Wednesday, when, in moving their adoption, Mr. H. Lord, the Chairman of the Gas Committee, said he hoped the members of the Council would carefully look through the report, in order to see the progress that had been made. He pointed out that a very important saving had been effected in the consumption of gas on the works. No less than £450 had been saved last year as compared with the previous year. The motion was seconded by Mr. F. S. Phillips, and adopted.

MARYBOROUGH (QUEENSLAND) GAS COMPANY.—The Directors of this Company, in their report for the half year ending June 30 last, state that the operations of the Company continue satisfactory. The amount at the credit of profit and loss account is £1682 12s. 2d., which the Directors recommend should be apportioned as follows:—Dividend for the half year at the rate of 10 per cent. per annum, £1251 7s. 6d.; for reserve fund, £100; and towards replacement of retort-benches, £200—leaving a balance to carry forward of £131 4s. 8d. Since the last half-yearly meeting, a new exhauster with engine and other appliances have been received, and are in course of erection. The construction of the new retort-benches (which has been carried out under the supervision of the Engineer, Mr. J. Henderson, C.E.) is also nearly completed. It is anticipated that when this new plant is brought into use, great advantages will result to the Company. The number of consumers is gradually increasing; and considerable additions continue to be made to the mains and services.

THE EDINBURGH AND LEITH GAS UNDERTAKING. MESSRS. LIVESSEY AND LASS'S REPORTS ON THE WORKS AND BOOKS OF THE COMPANY.

As intimated by our Edinburgh Correspondent in his "Notes" last week, the Gas Commissioners of Edinburgh and Leith have just issued, as a Corporation document, the joint and independent reports prepared for them by Mr. George Livessey, C.E., and Mr. Alfred Lass, F.C.A., and on the receipt of which by the Special Gas Committee of the Corporations, it was agreed to confirm the provisional agreement for the purchase of the undertaking by the towns.

The joint report (dated June 28) merely states that having considered the matter, and examined the Company's works and books, it was Messrs. Livessey and Lass's opinion that the terms of purchase set forth in the provisional agreement were "fair and reasonable in the interests of both the contracting parties."

MR. LIVESSEY'S REPORT.

This document (dated July 16) states that a visit of inspection was paid to the works by Mr. Livessey on June 28, when he found the general arrangement and condition of the works to be very good, and the surplus power in almost all particulars considerable. The report then continues: As in the case of the Edinburgh Gas Company, the manufacture is on land quite separate and distinct from that on which the gasholders are placed. The area occupied by the works is somewhat greater in proportion to the gas made than at Edinburgh; being rather over 2½ acres in extent. The maximum day's make last winter at the Baltic Street works was 1,986,000 cubic feet; while the maximum sent out in one day was 2,075,000 feet. The gasholder storage is 2,256,000 feet, which is considerably in excess of what is necessary. Where the gas is used mainly in shops and private houses, with no great preponderance of mills or manufactories (as in Edinburgh and Leith), it is not necessary to provide storage capacity in excess of the maximum consumption in 24 hours, or (say) equal to 100 per cent.; and when by the increase of consumption this is year by year reduced, it is found that the proportion may come down to 70 per cent. without undue inconvenience. But when this point has been reached, an additional gasholder should be erected, or existing gasholders telescoped, to bring up the storage to at least 100 per cent. of the maximum consumption. According to this rule, the Leith Company's storage of 2,256,000 feet is equal to 70 per cent. of a maximum consumption of 3,223,000 feet; and, therefore, it will not be absolutely necessary to increase the storage until the maximum consumption of last winter (2,075,000 feet) is increased by upwards of 50 per cent. I do not advise cutting it so fine, as in case of possible, but not probable, accident to one of the gasholders, with only 70 per cent. of storage, there would result a certain amount of loss and great inconvenience. I should, therefore, in good time telescope the two single-lift gasholders at Canonmills, which would add about 400,000 feet to the storage, and the cost should not exceed £4000. When further extensions become necessary, another gasholder of similar diameter, and 50 per cent. greater capacity (if made of three lifts, which is now common, instead of two lifts) can be erected on vacant land at Blandfield. The contents of the existing gasholder on that site are 1,125,000 feet. It is quite new, having been built in 1885. The largest gasholder at Canonmills is also comparatively new, dating from 1872—contents 750,000 feet—while the two others, of about 200,000 feet each, single lifts, are older but also in good condition.

The gas sold by the Leith Company has increased from 241,017,000 feet in 1878-9 to 358,627,000 feet in 1887-8—or, as nearly as possible, 50 per cent. in the nine years; while in the same time the unaccounted-for gas has come down from 13.87 per cent. to 7.63 per cent., which is strong evidence of good management, and that the distribution of gas has been well attended to.

It was, of course, impossible to inspect the mains supplying the various districts with gas. But the small amount of unaccounted-for gas, considering the very large mileage of mains in proportion to the gas sold, shows conclusively that they are in good order; and the low maximum pressures worked during the heaviest consumption of a winter's day, proves that the mains are of more than sufficient capacity for the efficient supply of gas to the consumers. The pressures above referred to are, I am informed, as follows:—Edinburgh district, 18-10ths; Leith district, 18-10ths; Stockbridge district, 19-10ths; and Granton low-level district, 26-10ths. With these facts before me, and having no reason to doubt that the Edinburgh Company's mains are also in a thoroughly good condition, I have no doubt, that by the amalgamation of the two undertakings, and the consequent re-arrangement of the districts supplied from the respective works, the distribution of the gas will be rendered even more efficient than heretofore. Duplicate mains will be removed; the aggregate mileage reduced; leakage still further diminished; and the supply of gas improved, to the advantage of the respective Corporations and the consumers.

Turning now to the manufacturing works, they are in appearance quite as crowded as those of the Edinburgh Company, as there is but little space uncovered with buildings. To some extent this is deceptive, as the area is practically considerably increased by the use made of the large and substantial stone buildings that formerly enclosed the now abolished gasholders. The whole of the purifiers are placed on an upper floor in part of these buildings; thus rendering the ground floor available for other useful purposes, and so in effect raising the total area available for the manufacturing station to about 3 acres. The site is eminently suitable for a gas-works; and as very little room is necessary for the storage of coke—the make of that article being regulated to the demand by increasing or diminishing the use of shale that yields but little coke—the whole available space should be used for the manufacture and purification of gas, which may be very largely increased on the land belonging to the Company. Mr. Linton has a plan for greatly facilitating the railway arrangements by abolishing the turntables, and bringing the railway into the works by a curve, which can be done by removing a station meter, which appears to me to be in the wrong place, to a more suitable position, where both meters can be placed side by side. There are four retort-houses, fitted with 256 retorts, heated on the Siemens principle, and 124 on the old system in No. 2 house, in which the retorts are circular, 14 inches diameter. In the other houses—No. 1, with 128, No. 3, with 56, and No. 4, with 72 large Q-shaped retorts, each 21 inches wide by 15 inches high and 8ft. 6in. long—the manufacture of gas can be conducted on the Siemens principle with much less fuel of a poorer kind; and higher and more regular heats can be maintained than under the old system. Thus, by means of the larger retorts carbonizing more cannel or coal, and producing more gas with charges of shorter duration, these advantages have proved so great that No. 2 house, with the old settings, has been thrown entirely out of use; and I believe it was the intention of the Company not to use it again until fitted up on the Siemens system. Last winter the greatest number of retorts in use was 192; thus leaving in reserve 64 of the Siemens, and the entire house of 124 set on the old plan—or, shortly, 192 retorts in use and 188 in reserve, in the depth of winter. There are coal-stores for 4000 tons, which, considering the railway facilities and the nearness of the collieries, is ample for a much larger make of gas than at present.

Passing over the condensers, engines and boilers, and exhausters with

the remark that they are of the best for their respective purposes, in good order, and like the retorts, equal to the production of over 50 per cent., more gas, I come to the purifying plant, which, I think, is capable of improvement. Mr. Linton is evidently of the same mind, as he has begun the remodelling of the purifiers. As to the scrubber-washers, I raise no objection, though it is doubtful whether they are better than the old-fashioned scrubber. Still they are efficient instruments, and of abundant power for the work to be done now and for some time to come. But I do not like the five sets of purifiers; necessitating the dividing of the gas into separate streams, and thus increasing the difficulty of controlling the process of purification. For a make of two, three, four, or even five million feet a day, I prefer, when practicable, passing the gas through only one set of purifiers. But in old works this is generally not practicable. As the make increases, additional sets of purifiers become necessary, as the old ones often cannot be enlarged. But the time comes at last when a clearance will be found to be advantageous; and this, I think, is the case at present at Leith, where the four smaller sets should be either abolished or converted into one set of large area—say four boxes, each 30 feet by 25 feet, or an area of 700 or 800 feet for each box, disposed or proportioned as may best suit the existing building. This would give a total area about the same as at present, and would be sufficient for many years to come.

I found the works well up to the mark in all the details so necessary for good results, and cannot conclude this report without saying that the whole arrangement and management does great credit to the Engineer.

MR. LASS'S REPORT.

In his report (dated July 6), Mr. Lass states that he has inspected the books of the Company over a period of ten years ending the 16th of May, 1888. He examined the accounts as made out on the Company's own system—remodelled in conformity with the Gas-Works Clauses Act, 1871, which latter was the form in which the accounts were put in evidence in support of the Bill promoted by the Company last year in Parliament. As his investigation proceeded, Mr. Lass found that the Company had from time to time during the ten years reduced the profits by charging to revenue account certain sums which should have been charged to "fixed plant" account. The profits were also further reduced by charging various other sums for depreciation, wear and tear, &c., which in the remodelled accounts had been written back; thus restoring the profits which had been originally taken. The following table shows the profits of the Company at the 15th of May in each of the specified years, on the two systems of account keeping:—

	Profits on Trading, as per Company's Books.	Profits on Trading, as per Remodelled Accounts.
1878	£12,461	£14,926
1879	12,489	14,570
1880	12,972	19,084
1881	10,903	14,630
1882	12,834	16,181
1883	13,850	18,713
1884	13,001	19,602
1885	12,922	21,627
1886	13,371	19,376
1887	19,475	22,250
1888	26,331	—

In two supplementary tabular statements, Mr. Lass gives the details of the revenue accounts, and shows the differences between the profits on trading under the two systems of account keeping. He then proceeds to answer the two questions:—"How is it that the profits in 1887 were £22,250, and in 1888, £26,331?" and "Have the profits for 1888, amounting to £26,331, been unduly inflated?" In reply to these questions, he first points out that in 1887 there was charged for abnormal parliamentary expenses £1901, and in 1881, £1121, but for which the profits on trading in these years would have been £24,151 and £27,452 respectively. To this he adds a table showing increases in receipts (under the ordinary heads) of £1838, £1425 of which was increased gas-rental, and £396 increased receipts for tar, coke, and waste lime; also another showing a total decrease in ordinary expenses, amounting (after subtracting various increases in expenditure) to £1413, the chief item in which is a saving of £1984 in the cost of coals. The total is thus brought out—

Total increase in receipts	£1888
Total decrease in expenses	1413
Total increase in profits	£3301

The next table shows the gradual increase in the sale of gas for the eleven years from 1878 to 1888; that of the former year being 232,218,000 cubic feet, and that of the latter year, 358,627,000 cubic feet.

Another table shows that, while in 1878 the quantity of coal carbonized was 27,594 tons, the quantity so treated in 1888 was 39,744 tons; the figures for the intervening years showing an almost uniform increase. On this point Mr. Lass remarks: "On reference to the foregoing, it will be seen that notwithstanding an increase in the quantity of gas sold from 349,767,000 cubic feet in 1887 to 358,627,000 cubic feet in 1888, and an increase in the number of tons of coal carbonized from 39,203 to 39,744, yet there has been a decrease in the expenses of 1888 compared with 1887 of £1984 in the cost of coal, and a further decrease of £380 in wages. These decreased expenses are the direct result of an expenditure on capital account in converting the ordinary furnaces into regenerative furnaces, which enables a cheaper class of coal to be carbonized with more beneficial results."

The following calculations show the working of the undertaking for the year ended May 15, 1888:—

Gas made	389,000,000 cubic feet.
Gas sold	355,865,000
Gas used on works	2,762,000
	358,627,000
Gas unaccounted for	30,373,000
	389,000,000 cubic feet.
Gas made per ton of coal carbonized	9787 cubic feet.
Gas sold per ton of coal carbonized	8954 "
Gas sold, per cent. on make	91.48
Gas used on works, per cent. on make	0.71
Gas unaccounted for, per cent. on make	7.81
	100.00
Cost of coal	14.83 pence per 1000 cubic feet sold.
Less—realized on sale of residuals	4.33 do.
Cost of coal, less residuals	10.50 do.
Working expenses	15.49 do.
Coal and working expenses, less residuals	25.99 do.
Gas-rental and meter-rents, realized	43.75 do.
Profit	17.76 do.

The working expenses of the Leith Company, therefore, amount (says Mr. Lass) to 15.49d. per 1000 cubic feet of gas sold; while those of the London and other Companies amount to the following:—

Average London Companies	12.89 pence per 1000 cub. ft. sold.
Do. London Suburban Companies	15.27 do.
Do. Gas undertakings (8) in hands of Local Authorities	11.61 do.
Do. Undertakings (10) in hands of Provincial Gas Companies	12.20 do.

It may, therefore, be taken that the answer to the second question is that "the working expenses charged against the revenue of the Leith Company for the year 1888, have not been unduly decreased for the purpose of inflating the profits."

With reference to the capital employed by the Leith Gas Company, the following calculations have been made:—

	Total.	Per Ton of Coal Carbonized.	Per Million of Gas Sold.
Capital employed as per Company's Accounts	£204,905 or £5 8 1	or £575	
Do. do. as per Remodelled Accounts	£265,329	6 13 6	715

The capital employed by the above-mentioned London and other Companies is as follows:—

London Companies	£5 11 3	£594
London Suburban Companies	6 7 10	663
Gas undertakings in hands of Local Authorities	6 3 2	666
Undertakings in hands of Provincial Gas Companies	5 9 8	564

Mr. Lass remarks that, on this showing, "it may be considered that such expenditure or capital employed, compares favourably with the expenditure or capital employed by other undertakings, especially looking at the following evidence given by the Company's Engineer (Mr. Linton), viz.:—that 'the works are competent for a manufacture of an amount of gas much beyond the present output.'"

The average profits for the two past years being £25,801, Mr. Lass thinks the maintainable profits of the undertaking may fairly be taken at £25,000 per annum, in which case the position of the Corporations will be as follows:—

Annuities at 9½ per cent. on £150,000	£14,000
Interest on debentures, 4 per cent. on £20,000	800
Interest on bank loan, 4 per cent. on £11,700	468
Interest on grassum, 4 per cent. on £11,000	440
Interest on working capital, 4 per cent. on (say) £20,000	800
Pensions (assuming that the whole will be paid)	1,050
Sinking fund ½ per cent. on £399,000 (capitalized value of annuities at 2½ years' purchase, which, at 9½ per cent., will provide £399,000 in 60 years)	1,995
Sinking fund, 1 per cent. on £62,700 (which, at 3½ per cent., will provide £62,700 in 44 years)	627
	£20,180

Leaving a surplus of £4820 per annum.

The interest on debentures, bank loan, grassum, and working capital (calculated at 4 per cent.), may, however, Mr. Lass considers, probably be reduced to 3½ per cent.

After showing that, by the agreement, the Company acquired a sum of £439,225, equal to about 31½ years' purchase of a dividend at 9½ per cent. on £150,000, or a perpetuity at 3½ per cent., Mr. Lass says: "Looking at the whole of the foregoing, I am of opinion that the terms contained in the provisional agreement for the purchase by the Corporations of the Leith gas undertaking are fair and reasonable to both contracting parties, and that the agreement should be confirmed."

THE GAS SUPPLY OF MIDDLESBROUGH.

Some interesting figures have recently been published dealing with the supply of gas by the Corporation of Middlesbrough, comparing the cost of the production of gas in winter and summer respectively—the difference in the demand being particularly marked in this northern town. Last January the make of gas reached to a little more than 33 million cubic feet; while in June the quantity was slightly over 12½ millions. The total manufacturing charges amounted in January to 1s. 7.34d. per 1000 cubic feet; and in June to 1s. 10.56d. The increase is found in most of the separate items—wages paid, for instance, having risen from 3.37d. to 3.85d. per 1000 cubic feet. On the other hand, residuals yielded a little more, to the extent of 8.87d., as against 7.31d. per 1000 cubic feet. The net price of the gas made was, therefore, 1s. 0.03d. in January, and 1s. 1.69d., in June. It is remarked that "the difference does not seem very large; but had the receipts for residuals been on an equality, it would have been larger, and even as it is, when spread over 20 or 30 million cubic feet, is important." In January, at the price at which gas was sold, there was a balance of more than 1s. per 1000 feet left to pay interest, redemption, and profit; while at June there was rather more than 10d. only to be so applied. In regard to these figures, our contemporary the *Engineer* says: "It is obvious that it is impracticable to obtain as large a consumption of gas in the summer as in the winter; but it is also evident that what is needed by the authorities in connection with gas-works is to aim to raise the consumption in the summer months by the fostering of the sale for purposes of heat, light, and power. The winter demand rises yearly; and as it does, it enforces a larger and larger provision for manufacture, storage, and distribution, and these facilities are necessarily idle in large degree in the summer. To utilize these facilities, especially for purposes of heat and power, means a double gain—it means a consumption in the summer, and it also means a day consumption at a time when the facilities would be otherwise unused. The utilization of the large resources of the companies and corporations producing gas would be a great boon to the commercial world; and it is to be aimed at in the way the official figures we have above summarized point out."

BELFAST CORPORATION GAS SUPPLY.—The monthly meeting of the Belfast Town Council was held on the 1st inst., when the Gas Committee presented a statement of their accounts for the year ended June 30 last. They showed a net profit of £12,535 3s. 1d., after providing a sinking fund of £7609 10s. 7d., and for depreciation on the gas stoves, meters, and lamps. This result the Committee consider very satisfactory, having regard to the fact that the price of gas was reduced by 3d. per 1000 cubic feet from the beginning of the financial year—the reduction representing a difference of nearly £10,000 on the year's profit. A balance of £5135 13s. 11d. was brought forward from the previous year to the credit of profit and loss account, out of which £3500 was contributed towards the cost of the erection of the temporary Albert Bridge, leaving a balance of £1635 13s. 11d., which, added to the net profit on last year's working, brings up the amount to £14,170 17s. The Committee recommended that £10,000 of this sum should be transferred to the reduction of capital account; and that the balance be carried forward to next year. Alderman Sir John Preston moved the adoption of the report and accounts; and this was agreed to without discussion.

THE GAS SUPPLY OF DUBLIN.

In the course of the proceedings at the Monthly Meeting of the Dublin City Council yesterday week, Mr. Dennehy called attention to the fact that there was no authority in the statute laws or bye-laws of the Corporation that would warrant or empower the Paving and Lighting Committee to engage any person at the rate of two guineas a day without having been previously authorized by the Council to do so; and he moved that the Paving and Lighting Committee report to the Council what are the facts and circumstances of such employment or engagement. Alderman Meagher stated that there was some friction between the Gas Company and the Inspector of Public Lighting. The latter made certain reports which were controverted by the Gas Company; and as the Committee looked forward to the matter being tested by a legal issue, it was decided, on the advice of the Inspector, that his opinion should be fortified by an expert, independent of the Gas Company or the Corporation, and accordingly a gentleman was so employed. The Lord Mayor said the standing order referred to salaries of persons who were permanently employed, and was not intended to refer to employment of a casual or temporary character in an emergency, as in the case before them. If the motion were carried, it might have the effect of seriously harassing or hampering the Corporation if the Gas Company had a battalion of evidence, whilst they (the Corporation) had only a solitary official. Mr. Dennehy agreed to withdraw his motion. Alderman Mulligan subsequently moved—"That the Paving and Lighting Committee be employed to name a Sub-Committee to take all necessary steps with reference to the supply of gas, and that the first standing order, being a resolution of the Council of 1851, be to this extent modified or rescinded." The Committee, he said, deemed it expedient to appoint a Sub-Committee to look after the gas supply, and to report from time to time with regard to the steps they took. Mr. Mayne remarked that, as there was some friction—as Alderman Meagher mentioned—between the Gas Company and some of the officers of the Corporation, he thought the Committee were perfectly justified in bringing forward this motion, which would provide for any contingency that was likely to arise. The motion was adopted.

TYNEMOUTH TOWN COUNCIL AND ELECTRIC LIGHTING.

At the Quarterly Meeting of the Tynemouth Town Council on Friday, the 31st ult., a discussion took place on a recommendation of the Trade and Commerce Committee that application be made by the Council for a Provisional Order for lighting the public buildings and streets with electric light. In January last, it should be stated, a new market was opened by the Corporation; and this is illuminated with the electric light, for which the ratepayers have had to pay dearly.

Alderman GREEN, in introducing the subject, proposed that the terms of the Committee's recommendation should be altered as follows:—"That a special meeting of the Council be convened for the purpose of considering the advisability of applying for an Order to light the principal streets and public buildings with electric light." He said that he wished to dissipate the notion that it was intended to enter upon any larger scheme of electric lighting than their present installation. Their object was simply to utilize the power they already possessed, and to make it a less losing concern than it was at present. He deprecated the idea that such a proposal would give rise to alarm in the borough on the ground of cost.

Mr. TATE seconded the motion.

Mr. DODDS observed that from the first he had regarded the introduction of the electric light into the market as ridiculous nonsense. He was still of that opinion. He urged upon the Council to let their first loss be the greatest, and not launch upon another scheme, the cost of which they could not foresee. He moved, as an amendment, that the whole matter be referred back to the Committee for further consideration.

Mr. ESKDALE, in seconding the amendment, said he was convinced that to rush headlong into expenditure over further electric lighting, would meet with the unanimous condemnation of the ratepayers. He held that Alderman Green's scheme meant additional apparatus, and not merely the utilization of the surplus electric energy and driving power which they already possessed; and he was persuaded, judging from past experience, that the promoters would not hesitate to carry any new power they might acquire to costly extremes.

After some further discussion,

Alderman GREEN, said the powers that the Corporation already possessed did not enable them to cross a street for the purpose of extending the electric light; and he insisted that his intention was to limit the application of the new illuminant to the corporate buildings, to portions of one or two of the principal streets, and to the new post-office, which was to be erected in the vicinity of the market.

The motion was ultimately adopted by ten votes to five.

THE CHELTENHAM TOWN COUNCIL AND ELECTRIC LIGHTING.

At the Meeting of the Cheltenham Town Council on Monday last week, a report was presented by the Committee appointed to consider the best mode of lighting a portion of the town by electricity. The position of the question may be thus briefly stated: About eight months ago, a Committee was appointed to report upon the advisability or otherwise of introducing the electric light into the town. The Committee led the Council to commit itself to the expediency of putting down an experimental installation over a restricted area, subject to its being carried out at a cost not disproportionate to the superiority of the light over that of gas. At Monday's meeting, Mr. Darby strongly opposed a minute of the Committee, which was to the effect that the electric lighting being adopted, and other things being equal, it was desirable that the supply of the light should be in the hands of the town rather than of a private company; and for the purpose of ascertaining the relative advantages and cost, it was desirable to employ an expert. He said that he declined to vote, with the information before the Council, in favour of the Corporation making themselves a trading body. In Birmingham, he said, a Provisional Order was sought for at a cost of £16,000, and then dropped, on account of the limit of time put down by the Electric Lighting Act of 1882. He concluded by moving an amendment to the Committee's report. At this stage of the proceedings, a letter was read from the Town Clerk to the Gas Company stating that, should the Corporation determine to submit the electric lighting to tender, it would be a satisfaction to them to be in a position to accept a tender from the Company, if they should be able and willing to tender. A long discussion followed; and eventually it was agreed that the Committee should, before any further step was taken, bring up an approximate estimate of the cost of lighting the experimental area.

The tender of Messrs. C. and W. Walker, of Donnington and London, has been accepted for the new gasholder to be erected in connection with the extension of the Perth Gas-Works. The cost of the holder will be about £9000; and it will probably not be completed till the autumn of next year.

THE THIRLMERE WATER-WORKS OF THE MANCHESTER CORPORATION.

At the Monthly Meeting of the Manchester City Council last Wednesday, the Mayor (Sir John Harwood), in answer to a question addressed to him, made a statement as to the present position of the Thirlmere water scheme. He said that the whole of the Thirlmere accounts would have to be recast, and placed on a uniform basis with regard to the repayment of the loans. Meanwhile, he might say that the Water-Works Committee hoped that they would be able to economize so that the whole of the interest on the money that had been expended would be provided without imposing any undue burden on anyone. The Committee would, as far as they could, distribute the entire cost on everybody who took the water, and not put the whole burden on the ratepayers. Alderman Lamb said he had often contended that the water-works never cost the ratepayers a single penny; and if the Thirlmere works had had a moiety of the gas profits, he did not think the ratepayers would have had to pay a penny now. The Mayor (resuming) explained that the Corporation were about to seek the sanction of Parliament for a proposal to raise the embankment at Thirlmere to the height of 20 feet only for the present, instead of the 50 feet their Act empowered the Committee to do. The Committee were of opinion that this change in the elevation would meet all requirements for the next ten, twenty, or possibly thirty years. It was besides in harmony with the wishes of all persons who took an interest in the Lake District of England; and would be conducive to the best interests of the Corporation.

NOTTINGHAM CORPORATION WATER SUPPLY.

ANNUAL REPORT OF THE COMMITTEE.

At the Meeting of the Nottingham Town Council yesterday week—the Mayor (Alderman Turney) presiding—the report and statement of accounts of the water undertaking for the year ending March 25 last were presented. They showed that there had been an increase in the revenue of £1127, and a decrease in the expenses of £561, as compared with the previous year. After paying the annuities and interest on loans and consolidated stock and the contribution to the several sinking funds, and putting aside £1000 for depreciation, the net profit available for disposal as the Council might see fit amounted to the sum of £749. The average profit made by the Corporation since the transfer in 1880 has been £3180 per annum, after payment of annuities and interest.

Alderman GRIPPER moved the adoption of the Committee's report and accounts. He said that it was satisfactory to note that they were this year able to report that, while the income had increased, the expenses had decreased. The report specified the net results; and therefore he was not going into detail to point out the whole of the items. The number of empties had increased by £284 over the previous year; but the not-collectable had decreased by £126. The collectable arrears had been £129; so that, putting the collectable and not-collectable together, they stood at a similar amount as in the previous year. After having paid the interest on the annuities and borrowed money, the Committee had actually saved, including interest accruing, during the eight years they had had the concern, £25,500 in round figures, or an average of £3180 per annum upon the undertaking. The amount in different years had naturally varied. In 1886, at the commencement of the enlargement of the works at Papplewick, they had a considerable reduction in the profits, inasmuch as they then began to pay the interest on the fresh outlay, from which they had not then received any benefit. They were now receiving a yearly increase from that outlay; and he did not think they could at present anticipate a reduction of profits to so low a point as in 1886. Everything was now going on satisfactorily; and he hoped would continue to do so. In conclusion, he said he thought there was an omission in the resolution he had to move. There ought to be added: "And that the sum of £700 be paid to the Finance Committee in aid of the district rate, and a small balance paid to the depreciation and renewal fund."

Mr. McCraith seconded the motion, which was adopted unanimously.

THE LIVERPOOL CORPORATION AND MR. HAWKSLEY.

At the Monthly Meeting of the Liverpool Corporation last Wednesday—the Mayor (Mr. T. W. Oakshott) presiding—a long discussion ensued on the presentation of the Water Committee's minutes, with regard to the award in the recent arbitration with Mr. Thomas Hawksley, C.E. The terms of the award of the Arbitrator (Mr. Bosanquet, Q.C.) were given in the JOURNAL last week, p. 429.

Alderman BOWER, in moving the confirmation of the Committee's proceedings, referred at length to the circumstances which necessitated the arbitration with Mr. Hawksley. With these our readers are already fully acquainted. He then went on to say he was very sorry to inform the Council that, contrary to the anticipation of their Counsel and of everybody who was interested in the arbitration on behalf of the Corporation, there had been a larger amount awarded against the town than they expected. He was not going to say anything against the award; at the same time, when first he heard of it, he was under a strong impression that the Arbitrator had forgotten the last sum of £11,000 paid to Mr. Hawksley. However, that was not so; and, the award having now been made, he felt that the right thing was to accept the position. It had been stated that the award, or the cause of the arbitration, led to a loss to the city of something like £40,000. He would remind the Council that in January, 1885, Mr. Hawksley made a return stating that the probable total expenditure upon the works would be £2,163,750. That was supposing the works had been carried out under that gentleman's directions. Taking from this sum £277,750, the cost of land, &c., in respect of which no commission was to be paid, there remained £1,886,000, on which, according to Mr. Hawksley's return, they would have had to pay him commission. Therefore Mr. Hawksley, if he had continued at the work and spent that amount, would, at 2½ per cent. commission, have been entitled to £47,160. The actual state of the case was that the amount paid to Mr. Hawksley was £20,617; and they had already paid to him the amount of the award—£14,123. If he admitted the costs of the arbitration at the large sum of £4000 (which he had reason to believe would be considerably above the amount), it would show that they would have spent now £38,740. In other words, by Mr. Hawksley breaking off his work in the way he had done, the Council, having all his plans and everything with which to finish the work, and the work being now nearly completed, the town, instead of losing £40,000 by these proceedings, would benefit to the extent of £3420. In the arrangement first entered into with Mr. Hawksley, it was suggested by him that Mr. Deacon should receive 2 per cent. and Mr. Hawksley himself 3 per cent. commission. If this had been carried out, the commission of both Engineers would have reached the sum of £94,235; Mr. Hawksley's 3 per cent. commission amounting to £56,595, and Mr. Deacon's share, to £37,780. Whereas now the Corporation would only have to pay under the agreement and the award, £38,740. To this sum there must be added £12,500 paid to Mr. Deacon in salary and expenses; making the total £51,345. Therefore, in comparison with what Mr. Hawksley originally asked the two Engineers justly should take, and

even taking the award against them, there was a saving to the Corporation of £42,985. Much as he regretted that the incompatibility between the two Engineers should have been increased by discussions in the Council, and much as he regretted that circumstances should have led to the separation from the work of Mr. Hawksley, the fact was, taking the most unfavourable view towards the Liverpool Corporation, that a saving had been effected by Mr. Hawksley's leaving, of at least £8000.

Mr. O'HARE complained of the way in which this matter had been brought before the Council. He thought some means should have been taken by the Water Committee to avert a litigation which had ended so disastrously to them, and involving between £30,000 and £40,000. If it was within the range of possibility that Mr. Hawksley would succeed in his claim, then it was their duty as public servants to try and compromise the claim, and meet it half way, rather than have to pay from £30,000 to £40,000.

Alderman BOWER explained that not only was Connell's opinion taken, but the Water Committee empowered him to try to compromise the matter with Mr. Hawksley. He made three journeys to London to attempt to arrange the matter with Mr. Hawksley; but they could not arrive at any compromise at all.

Mr. O'HARE considered in a case of this kind that it would be more satisfactory if they received the fullest documentary information that the Water Committee could afford them; and he proposed that the submission and award be printed, and that a copy be sent to each member of the Council.

Sir JAMES PICTON seconded Mr. O'Hare's motion.

A long discussion followed, in the course of which some members expressed the opinion that a mistake had been made at the outset in appointing two Engineers in connection with the Vyrnwy works; while others protested against the Water Committee being blamed for what had taken place.

The TOWN CLERK afterwards pointed out that Mr. O'Hare's motion would not obtain for him the information he desired.

Mr. O'HARE thereupon said that, after the long discussion they had had, he would withdraw his motion.

The proceedings of the Committee were then confirmed.

THE WATER SUPPLY OF BELFAST.—The connection between Stoneyford and the Lagmore reservoir of the Belfast Water Commissioners has now been completed. The culvert is 7 miles in length; and the Contractors (Messrs. Fitzpatrick Bros.) have earned the bonus of £1500 offered for its completion within a specified time. The Commissioners are now considering a scheme for the filtration of the entire water supply at a cost of about £60,000.

LEWES GAS COMPANY.—The report submitted at the half-yearly meeting of this Company last Wednesday stated that the revenue account showed a profit for the half year of £1353 19s. After providing for interest on mortgage bonds, the balance of net revenue, as shown in the profit and loss account, was £1652 6s. The Directors recommended that a dividend of $\frac{1}{2}$ per cent. be declared, amounting to £1209 12s., and leaving a balance of £442 14s. to be carried forward. The report was adopted.

BATH GASLIGHT COMPANY.—A very satisfactory increase in gas-rental, compared with the corresponding half of last year, was experienced by this Company during the six months ending June 30. The amount received for gas from private consumers and public lamps was £24,736 19s. Residuals realized £3969 16s.; and this also compared favourably with the June half of 1887. The total revenue in the six months was £29,342; and the expenditure, £20,324. The balance of net profit to be carried forward, subject to the half-year's dividends to June 30, is £8711. The Directors reported that an additional lift is being added to one of the holders. At the meeting of the shareholders on the 31st ult., the Directors' report was adopted, and maximum dividends declared.

HARROW DISTRICT GAS COMPANY.—Reporting upon the operations of this Company during the half year ending June 30 last, the Directors state that the reduction in the price of gas at Lady-day of 3d. per 1000 cubic feet has affected the rental to the extent of about £30. They trust, however, that the increased consumption, in consequence of the reduction, will soon re-establish the usual rental. The balance on profit and loss account is £1673 14s., out of which the Directors recommend the declaration of a dividend at the rate of $\frac{7}{8}$ per cent. per annum on the original "A" capital, of 7 per cent. on the first additional "B" capital, and of $\frac{5}{8}$ per cent. on the second additional "C" capital, all less income-tax. The revenue account shows that the receipts in the half year amounted to £3965, and the expenditure to £2415.

THE PROPOSED NEW WATER-WORKS FOR PADHAM AND HAPTON.—Last Tuesday a special meeting of the Padham and Hapton Local Board was held to adopt an amended estimate of the cost of completing the new water-works at Churn Clough; and to authorize an application to the Local Government Board for permission to borrow a further amount of £26,100, and to withdraw the application for £32,000 agreed to last December. The Clerk gave a brief review of the history of the water-works scheme since the holding of the Local Government Board inquiry in May, and the interviews which the Engineers and deputation from the Board had had with the Inspectors of the Local Government Board. He also pointed out the suggestions which had been made by the Inspectors; and the consequent change in the estimate arising from a deviation from the original scheme. He added that the deputations were of opinion that the matter could not be arranged by correspondence. The resolution proposed to be adopted was to withdraw the application for sanction to borrow £32,000, and ask for £26,100 for the completion of the construction of the works; and this was agreed to by the Board with only one dissentient.

THE PUBLIC LIGHTING OF CHILVERS COTON (NEAR NUNEATON).—At a recent meeting of the Chilvers Coton Local Board, a discussion took place in reference to the way in which the gas-rate should in future be levied; it being felt by those who have been accustomed to pay it, that the farmers in the outlying portions of the parish (where there are no public lamps) ought to contribute something towards the cost of the lighting, inasmuch as they derive benefit from it when passing through the lighted area in the evening. On the other hand, many of the outsiders object to contributing towards the cost of the public lighting; contending that they get no benefit therefrom. The Clerk of the Board was accordingly instructed to communicate with the Local Government Board, asking if a 6d. gas-rate might be levied over the present lighting area, and the balance taken from the general district rate; it being stated that this would probably be satisfactory to the outlying ratepayers. A reply has just been received from the Local Government Board, in which it is pointed out that, under section 211 of the Public Health Act, 1875, the proposal of the Local Board cannot legally be carried into effect. The Board will therefore continue the lighting, for the ensuing season, as heretofore; the cost of it falling upon those residing within the area in which the public lamps have been erected.

NOTES FROM SCOTLAND. (FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.
In the course of the four months ending with August, the amount of gas-rental collected in Dundee was £9532, which is £246 more than the sum collected at the same date last year. At a meeting of the Gas Commissioners on Wednesday, the Finance Committee recommended that Mr. A. I. Strachan, who has long been Chief Clerk in the office, should be appointed Treasurer, in room of the late Mr. Matthew, at a salary of not less than £300; and they asked the Board to remit to them to report on the Treasurer's duties, and as to the changes which should be made in the office staff consequent on Mr. Strachan's promotion. The recommendations were unanimously agreed to; and Mr. Strachan's security was fixed at £1000.

It is announced that an oil-gas works is being erected at Cowdenbeath, a mining centre in Fifeshire. About 25 years ago, there were only one or two houses by the roadside, where now there is a town of 5000 inhabitants. The scheme is being promoted by a Mr. Alexander. This gentleman recently opened a shop at Cowdenbeath; and, being convinced of the advantages of oil-gas over the ordinary paraffin-lamp, he at once brought the matter before a number of business men in the rising village. Assured of support, Mr. Alexander put himself into communication with the Patent Paraffin Gas Lighting Company, Limited, of Glasgow; and the erection of the works was shortly afterwards commenced. The gasholder, it is stated, will be about 1200 cubic feet capacity, which may appear small; but it is pointed out that the gas is about 60-candle power, and therefore the 1200 is equal to $2\frac{1}{2}$ times that amount, or say 3000 cubic feet of the ordinary coal gas supplied in Scotland. Already about 200 yards of 4-inch pipes have been laid; and service-pipes therefrom to several persons who have contracted for a supply of the gas, and arrangements have been made for laying a 3-inch main in the footpaths on both sides of the street.

The estimate for the lighting of the City of Edinburgh for the current year has been made by a Town Council Committee; and it amounts to £14,445, or £230 more than last year.

The statement of accounts to be presented to the shareholders of the St. Andrews Gas Company at their meeting next Wednesday shows that the income during the year ending the 31st ult. was £3971 8s.; and the expenditure £2908 9s.—leaving a balance of £1062 19s.

Last year the Police Commissioners of Dalkeith had before them a proposal to acquire the gas-works, and rejected it as being too risky, in view of the advance of electric lighting. They have now appointed a Committee to consider the question of introducing electric lighting into the borough. The gentleman who introduced the subject urged its advisability on the ground that, with a large gas-engine, which is used in pumping water, not fully employed, there was a surplus of power which might be utilized in driving dynamos. The query which naturally arises in one's mind is whether if, in a place of the size of Dalkeith, the Commissioners cut off their consumption, it will be possible for the Gas Company to go on; and in this event, whether it might not have been more sensible rather to acquire the gas-works in the first instance, and then have considered the feasibility of introducing electric lighting.

The Water Committee of the Aberdeen Town Council, at their meeting on Tuesday, had under consideration the estimate of the income and expenditure for the year 1888-89. Last year the revenue was £15,710; and the expenditure £15,805, leaving an adverse balance of £95. From the previous year, however, a surplus amounting to £945 was carried forward, so that the year ended with a balance to the good. For the coming year the estimate shows a slight increase on wages; and there will be an increase also on the amount paid as interest. The sinking fund will also show a rise; and it is calculated that at the present rate, which the Committee agreed to continue, all the existing surplus will be required, and that next year will close with an adverse balance of £55.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.
After passing over August as a holiday month, the Glasgow Corporation Gas Commissioners had an "innings" at the Town Council meeting on Thursday. The annual report of the Gas Committee, a full summary of which has already been given in the JOURNAL (*ante*, p. 301), was submitted by Baillie McLaren, Convener of the Sub-Committee on Finance, who moved its adoption. In the course of his remarks, he pointed out that the proposed reduction in the price of the gas from 2s. 10d. to 2s. 8d. per 1000 cubic feet would give a benefit of £18,000 to the community of Glasgow and the suburbs. He also stated that, during the past five years, the Gas Trust had reduced the price of gas to such an extent that the consumers had benefited by upwards of £110,000. Baillie Macfarlane, in seconding the motion, remarked that the average illuminating power of the gas during the year 1887-8 had been 23.1 candles. It was not intended to make any change in that respect. He stated that while the works generally were in a very fair condition, the Committee intended to remodel the Tradeston or South-Side works; the expense involved in the alterations and extensions to be spread over a period of two or three years; and for this purpose the sum of £12,000 had been written off the value of the Tradeston works. The report was adopted; and the Committee's minutes were approved of.

Baillie Shearer was present at Thursday's meeting of the Glasgow Gas Trust; but he did not submit the motion of which he gave notice several months ago, to the effect that he would ask a vote of £5000 from the gas surplus profits for the benefit of the "Common Good;" indeed, he seems to have quietly acknowledged that the Gas Committee had taken the "wind out of his sails," as they had so dealt with the year's profits of the gas undertaking as to leave only a net surplus of £5201 2s. 2d. to carry forward to next year's account.

The resolution to reduce the price of Glasgow gas to 2s. 8d. per 1000 cubic feet will at once take effect; and in accordance with the practice of past years, the Directors of the Partick, Hillhead, and Maryhill Gas Company will at once "follow suit," and also supply their consumers with gas at the price just mentioned.

Business has been done during the week in the ordinary shares of the Partick, Hillhead, and Maryhill Gas Company at 89s. per £5 share.

The Falkirk and Larbert District Water Trust have now set to work in right earnest to carry out the terms of the Water Act that was passed in the last session of Parliament. Mr. W. R. Copland, C.E., of Glasgow, who prepared the scheme for the consideration of Parliament, has been appointed by the Trustees to carry out the works which are contemplated in the Act; and he is now engaged in preparing the plans and specifications, which are expected to be ready in November, so that there is a reasonable prospect that the contractors who may be entrusted with the execution of the necessary works will be ready to begin operations early in the ensuing year. Mr. Copland is sanguine enough to believe that within two years from the time of commencing the works a supply of water will be available for the entire district, while a portion of the district nearest the source of supply may be having the water at an earlier period. Mr. Wilson, Town Clerk, of Falkirk, has been appointed *ad interim* Clerk to the Water Trust.

The completion of the Camphill scheme for extending the water supply of Paisley may now be regarded as an event of the early future. The scheme was inaugurated several years ago; and from the fact that the Contractor, Mr. R. B. Stewart, has somewhere about 200 men employed on the works, it may naturally be concluded that the extension works in hand is a very important undertaking. When it was decided by the Paisley Water Commissioners to construct the Camphill reservoir, which is expected to bring their storage capacity up to 1519 million gallons, they had in view the fact that they would be able to make such provision for the manufacturers of the town, and the community generally, that they would be beyond the chance of want for many years to come. The reservoir is formed in the glen through which the Rye Water flows. The embankment thrown across the glen was 55 feet high when the reservoir was opened two years ago; and it is contemplated to raise it another 25 feet. The collecting ground extends to an area of about 6800 acres.

Messrs. Osborne and Stevenson, of Pollokshields, Glasgow, have been successful in gaining the contract for the construction of the water-works extensions for the town of Gourrock; their tender amounting to £1650. The works are to be commenced at once.

The Glasgow pig-iron warrant market has been more active within the past few days than in any week of the past half year. There is a large amount of legitimate trade passing, and several special brands have been in requisition, with the result that in nearly all cases prices have been advanced. America has been buying more freely than for some time past. The stocks of pig-iron in the public warrant stores have only increased to the extent of 124 tons during the week; the ordinary make being practically all absorbed. On Monday the price of Scotch warrants opened at 41s. 4d. per ton cash; and up to 42s. 3d. per ton was subsequently reached. "Bears" bought largely on Wednesday to cover oversold accounts; more than 50,000 tons changed hands, and 42s. 3d. per ton was again touched—the highest rate since the spring. There were realizations for profits on Thursday; and there were evidences of considerable strength in the market. Yesterday the tone was decidedly weaker, down to 41s. 7½d. per ton cash buyers being quoted at the close. Hematite and Cleveland have been very strong all the week.

The improving tone in the coal trade still continues, especially in the export department, and a brisk business is now doing at the Clyde and Ayrshire ports. For main coal the quotation has reached 6s. per ton f.o.b. at Glasgow coaling cranes. The demand for furnace qualities is on the increase; and prices are responding to the better feeling in this branch of the trade. For house coal there is a good steady demand; but the prices have not made any upward move in consequence.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Sept. 8.
Sulphate of Ammonia.—There has been a fair "spot" demand, but hardly sufficient to raise values; and to-day the feeling is very quiet again. There is, therefore, practically no change in the quotations; the position is in no way altered. The inquiries for future delivery, principally from the end of the year to March next, have been on a larger scale; but the limits are too low to tempt makers, and so the orders have been taken by speculators. The anxiety to secure forward contracts, at moderate rates, seems to be generated by the higher quotation of nitrate for Sept.-Oct. shipment; and freights are still rising. As regards the actual position of this commodity, the visible supply (including stocks and cargoes afloat) is about 50,000 tons in excess of that at the same time last year. The total shipments the first eight months of this year were 370,000 tons, against 310,000 tons for same period of 1887; while the consumption does not seem to have materially increased.

LONDON, Sept. 8.
Tar Products.—There has been no important change in the position of this market during the week. The demand is fairly good, considering the time of year. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. 1½d. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 9d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 4d. per gallon. Cresylic acid, 9d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 6d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—There is a slightly better feeling in the sulphate market; but this article still "hangs fire." It has changed hands during the week at an advance of several shillings on the previous week's sales. Prices: Sulphate of ammonia, £11 5s. to £11 7s. 6d., less discount. Gas liquor (5° Twaddell), 7s. 6d. per gallon, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 1½d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Sept. 8.]

Sulphate of Ammonia.—The market is still in a very abnormal state; and the shyness of Continental buyers is by many attributed to the action of Beckton in lowering their prices. Liverpool values are still above those obtainable at Hull; and there is still but little offering for prompt delivery. Leith is well supplied with orders; and makers are eagerly following the course of the market, with the intention of making their September-December sales. Beckton prices stand at £11 5s.; London outside makes, £11 8s. 9d.; Liverpool, £11 10s.; Hull, £11 7s. 6d.; Leith, £11 5s.

Tar Products.—The benzol market remains much in the same inactive state as has characterized it for some months past. The fact that 90's benzol has not risen or fallen lately is due to there being not a tithe of the quantity made by carbonizing which was projected at this time last year; and yet, with this wonderfully diminished production, it has scarcely been able to hold its own. We have no hesitation in saying that should ever the quantity be required, four times the quantity of benzol could be produced that has been made during the past six months. The price of 90's is variously quoted from 2s. 10d. to 3s., and 50/90's at 2s. 4d. Pitch remains without change in value; but it has been in fair demand lately at old rates.

LIGHTING OF THE TEES WITH GAS.—At the meeting of the Tees Conservancy Board yesterday week, the scheme for lighting the river with compressed gas, which has received the approval of the Commission and of the Trinity House Brethren, was, on the recommendation of the Works Committee, ordered to be proceeded with in accordance with the Engineer's report, at a cost not exceeding £1800.

SOUTH STOCKTON GAS SUPPLY.—Some time ago the South Stockton Local Board applied to the Stockton Corporation to have the price of gas in South Stockton reduced to the same price as in the municipal borough—namely, from 2s. 8d. to 2s. 6d. per 1000 cubic feet. The Gas Committee, at the meeting of the Town Council last Tuesday, reported that they could not see their way to make the suggested reduction.

SALE OF SHARES.—A number of "A" and "B" shares in the *Cleveland Gas Company* were recently disposed of by auction at average prices of £16 7s. 6d. and £14 10s. 6d. respectively.

METROPOLITAN GAS COMPANY OF MELBOURNE.—At the half-yearly meeting of this Company held on July 27, a dividend at the rate of 17 per cent. per annum was declared; £20,000 was added to the reserve fund (raising it to £133,750); and £33,433 was carried forward.

REDUCTIONS IN PRICE.—The *Oswaldtwistle Local Board* decided, at their meeting yesterday week, that the price of gas to consumers of 400,000 feet and upwards in six months should be reduced to 2s. 10d. per 1000 cubic feet, and to consumers of less than that quantity, 2s. 11d. per 1000 cubic feet, with 5 per cent. discount if paid for on or before the last day of the month following the end of the quarter.—The proprietors of the *Bungay Gas-Works* have notified to their customers that, in order to encourage the further consumption of gas, the price will be reduced from 5s. to 4s. 6d. per 1000 cubic feet, on and after the 1st prox.—The *Workington Local Board*, at their last meeting, resolved to reduce the price of gas, on the 1st prox., from 2s. 11d. to 2s. 8½d. per 1000 cubic feet.

THE INTRODUCTION OF GAS IN GLASGOW.—Our Glasgow Correspondent, writing on the 1st inst., says: "Just 70 years ago to-day (in 1818), gas was introduced into the street lamps of Glasgow for the first time. A notice of the event appeared in the *Glasgow Herald* (then a small four-page sheet, published bi-weekly, at 7d.) of the following Friday. The notice ran as follows:—'For the last three evenings a part of Trongate, and a number of shops in the town were lighted with gas. The appearance was highly beautiful, particularly last night; and when the Company are enabled to carry fully into execution their whole plan, we anticipate, from the broadness of our streets, it will have a grand effect. Some malicious persons having removed one of the burners on Wednesday evening, a reward of ten guineas is offered for such information as may lead to their conviction.'"

NORTHERN COAL TRADE.—The improvement in the northern coal trade continues; and there have been contracts decided at advanced prices during the past few days. Steam coals have been steady, at prices which vary from 7s. 6d. to 7s. 9d. f.o.b. in the Tyne for best qualities; second qualities being lower. For gas coals, the demand is large and growing. Some interest has been felt in the decision as to the contracts of the Newcastle Gas Company. Most of the coal was offered at prices varying from 6s. to 6s. 6d. The Directors of the Company made a counter-offer at a price which is 3d. per ton above that of the past year, or about 6s. 1½d.; but this offer has not as yet been accepted. It is quite probable, however, that this will be about the price on the average; and coal delivered at this rate must be held as cheap. Other contracts show a slight advance; so that it must now be concluded that an advance in gas coal, both sales and contracted, may be regarded as established. Manufacturing coal is dearer; but household coal is dull.

DOVER GAS COMPANY.—At the half-yearly meeting of this Company on Monday last week, the statement of accounts presented showed that the receipts for the six months ending June 30 amounted to £13,448, and the expenditure to £10,821; leaving a balance of £2627. The Chairman, in moving the adoption of the Directors' report, alluded to the fact that notwithstanding the 3d. reduction made in the price of gas in January, the profit for the half year was sufficient to pay the full parliamentary dividend. They had also announced a further reduction of 2d. per 1000 cubic feet as from July 1 last. With reference to the accounts, the reduction in price made at the commencement of the year took from the gas-rental the sum of £900; but with the increased consumption of gas, which was 3·37 per cent., the revenue from the sale of gas was only less by £547 15s., as compared with the corresponding period of last year. Then the residuals had increased £223 17s.; coke and tar had realized £100 more; sulphate of ammonia, £123 extra; stove-rentals, £12 9s.; and the interest on the reserve fund investment was more by £41 1s. 2d. The total revenue had increased by £270 17s., compared with the corresponding half of last year. The total expenditure, notwithstanding the increased quantity of gas sold, was less by £168. The manufacture of gas and residuals under the management of Mr. R. Herring had, he said, been most satisfactory. The report was adopted; and a dividend declared at the rate of 7½ per cent. per annum, less income-tax.

RESUMPTION OF THE CONSTANT SUPPLY OF WATER AT LIVERPOOL.—Yesterday week, the usual meeting of the Water Committee of the Liverpool City Council was held, when the proceedings of the Executive Committee included the following report, which was presented by Mr. Parry, the Engineer of the Rivington works:—"The volume of water now in store at Rivington is 1547 million gallons, which is equal to about three months' supply at the present rate of consumption. Though this is an increase upon the volume in store at the corresponding date last year, it is still very considerably less than the usual contents of the reservoirs in the month of September. Since the restoration of constant service in the year 1875, the average quantity of water in stock at the beginning of September has been 2679 million gallons. The present stock of water is therefore 1132 million gallons below the average of the last twelve years; and if the exceptional experience of last year were repeated, the reservoirs would fall to an undesirably low level in the coming winter. The resources of the Committee at Rivington are thus still deficient; but having regard to the supplemental supplies which have been provided, and especially considering the importance to the community of restoring a constant supply at the earliest possible date, I think that the Committee may safely resume the constant service as soon as due notice of the change can be given." It was resolved that the constant supply should be resumed on the following Thursday, and this was accordingly done.

MORECAMBE GASLIGHT COMPANY.—At the annual meeting of this Company on the 31st ult., the Directors reported, with sincere regret, the death of their Chairman (Mr. Alderman Roper), in whose place they had appointed Mr. R. Briggs. They also stated that the capital account had been overdrawn to the amount of £639 17s.; and in order to meet this, they proposed making a call of £1 per share on the 800 old shares of the Company. The revenue received during the past year was £3292 17s.; and the expenditure was £2213. After payment of mortgage interest, the profit amounted to £875 15s., which, with the balance from last year (£825 4s.), made a total of £1700 19s. An interim dividend of 3½ per cent. was paid on March 1 last; and a similar dividend was declared at the meeting—making 7 per cent. for the year, free of income-tax. In moving the adoption of the report, the Chairman stated that the new retort-house and six purifiers which they had been erecting were now completed. The amount expended upon them was £4438 16s. 9d., less £400, which has been debited to revenue account in consideration of the old purifiers and old bench of retorts which would have had to be renewed out of the revenue; so that the cost of the extensions stood in the Company's books at £4038 16s. 9d. These extensions, he said, were giving every satisfaction, and would enable the Company to send out double the quantity of gas. Votes of thanks were passed to the Chairman and Directors, and to the Manager (Mr. W. Duff).

A "SUBSTITUTE FOR GAS" TO BE FOUND AT CASTLEFORD.—At the last ordinary meeting of the Castleford Local Board, in consequence of the Gas Company having positively declined to make any reduction in the price of gas supplied to the Board, it was resolved, on the recommendation of the Finance Committee—"That the Clerk make inquiries as to the feasibility and cost of providing a substitute for gas."

CHICHESTER WATER-WORKS COMPANY.—A very favourable report was presented by the Directors at the recent half-yearly meeting of this Company. It stated that the receipts from water-rents during the last three half years have been as follows:—For the half year ending June, 1887, £1143; December, 1887, £1187; June, 1888, £1184. The profits for the past half year amounted to £753 11s., which, together with the balance of profits brought forward from the previous half year, made a sum of £1701. Out of this a dividend of 7s. 6d. per share on the fully paid-up shares, and of 6s. per share on the partly paid-up shares (£8 paid), free of income-tax, was declared on Feb. 23 last, amounting to £710. After carrying £200 to the reserve fund, there remained a balance of £880, from which the Directors now recommended an interim dividend of 8s. 9d. per share on the fully paid-up shares, and of 7s. per share on the partly paid-up shares; being at the rate of 8½ per cent. per annum, free of income-tax. The report was adopted.

THE GAS QUESTION AT FLEETWOOD.—The Committee recently appointed at a meeting of Fleetwood ratepayers, to inquire into the methods and cost of lighting in other towns, have had several meetings to consider proposals from electric lighting and other companies; and when the sanction of the Board of Commissioners has been obtained (and it will probably be granted to-morrow, Wednesday) the Committee will proceed to towns to which they have been invited, to examine modern systems of lighting. The inducements to adopt the electric light are said to be locally very strong; and it is probable that for street illumination the Committee may recommend the formation of a Company to undertake the lighting of the town by electricity. Failing the electric light, the system patented by the Automatic Gas-Oil Company will have a favourable report from the Committee, as the proprietors of this process have offered to enter into a contract to light the town as effectively as at present, for 25 per cent. less than is being paid to the Gas Company.

REFUSING TO SUPPLY WATER.—At the Thames Police Court on Tuesday last, the Secretary of the East London Water-Works Company (Mr. I. A. Crookenden) was summoned at the instance of Mr. J. H. Johnson, of St. Ann's Wharf, Limehouse, for refusing to supply water to two houses belonging to him. The complainant said that the reason the Company gave for refusing a supply when requested to do so was that he declined to put in storage cisterns. Mr. George Keble, on behalf of the Company, maintained that they were only within their rights in not giving complainant a supply, as he had not conformed to the several sections of the Acts of Parliament bearing on the matter. Before a supply was given, the Act provided for the putting in of a cistern to store the water; and if it was not done, they had power to discontinue the supply. Mr. Lushington considered that the complainant was entitled to a supply, but consented to have the case adjourned for a fortnight to have the fittings examined; the Company in the meantime undertaking to lay on a supply without prejudice.

NEW WATER-WORKS FOR LIMERICK.—Last Wednesday the ceremony of turning the first sod of the new water-works which the Corporation of Limerick are about to construct at Clareville was performed by the Mayor, by the aid of a silver spade which was presented to him by the Engineers and Contractors. The new works, it is stated, will cost £35,000, and are based on a turbine scheme devised by Messrs. Cruise, Browne, and Fogarty, Engineers, of Limerick. Mr. Dixon, of Dublin, has been appointed Contractor for the works of construction to the extent of £16,000. It is estimated that the works will take from eighteen months to two years to complete; and the cost of working, after completion, is put down at £500 annually. The scheme is in the first instance propulsion and elevation by a system of turbines on the Shannon, near the Falls of Doonass. The water thus raised will be stored at Newcastle Hill, in a reservoir having a capacity of 70 million gallons. The reservoir will be at such an elevation as will secure a constant supply to the city of 1½ million gallons daily; and the pressure will be sufficient to force the water over the top of the highest house in Limerick. After the ceremony, the Engineers entertained the representatives of the Corporation and other guests at luncheon.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,

ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.
TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 300,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, SEPTEMBER 18, 1888.

THE BRITISH ASSOCIATION REPORT UPON STANDARDS OF LIGHT.

It would be pardonable if photometrists had forgotten the existence of the British Association Committee on Standards of Light, seeing that this Committee was nominated several years ago, and has never done anything very definite towards settling the questions which its members have taken into consideration. The Committee presented their final report at the recent Bath meeting, however, and have thus terminated their labours, which demand some notice at our hands. Their conclusions are not of a startling character, since they merely confirm those stated by Mr. Dibdin in his report to the Metropolitan Board of Works. This is gratifying, as it is rare for photometrical research committees to corroborate each other. Mr. Dibdin's report is, therefore, endorsed by independent authority as being the exposition of the truth as regards photometrical standards; and perhaps when the

London County Council settles into work, it will be acted upon, to the final extinction of the discredited standard candle. The ground covered by the British Association Committee is the same as that on which many other photometrists have laboured before them. They took samples of standard candles of different makers, including one special kind submitted for examination, and they compared them with pentane and the amyl-acetate lamp. With regard to candles, they arrived at the conclusion that they are not worthy of being called a standard, for the same reasons that have often been advanced to their discredit. Briefly, it is found that there is no connection whatever between the parliamentary definition of a standard candle and its illuminating power. Spermaceti does not mean any definite chemical composition—and, besides, candles are never made of spermaceti alone. There is no definition for the constitution or material of the wick; so that so-called standard candles, conforming to the terms of the law, can be made which nevertheless vary largely in illuminating power. It is stated in the report that, in the preparation of spermaceti for candle making, considerable improvements have been made of late years, which introduce a source of possibly grave error in photometry by the standard candle. The manufacturer's object is to separate his spermaceti, in as dry a condition as possible, from the liquid which accompanies it while in the crude state, and which is sperm oil. Modern processes which have been adopted with this view have resulted in the separation of a drier solid, with a higher melting point, than was obtainable even ten years ago. The increased difficulty of burning this dry spermaceti has necessitated the use of larger wicks in the candles, which consequently give less light than the old candles consuming the same weight of material with small wicks. It may be remarked here that this conclusion differs from that arrived at by some photometrists, which is that standard candles give more light now than formerly. The Committee emphasize the observations that the illuminating power of candles is materially affected by the conditions as to ventilation under which they are burnt.

The Committee naturally have something to say about the Violle standard of light, which was so enthusiastically adopted by the International Congress of Electricians that met in Paris some years ago, and has never been used by anybody but its author. The way in which this recommendation of the Congress has been ignored is a striking commentary upon the futility of such formal certificates, although issued by the highest authority, when unsupported by substantial advantages. Nobody has ever been able to make use of the Violle standard, except M. Violle himself; and when Mr. Dibdin wished to try it in the course of his own exhaustive inquiry, he could not even obtain the apparatus. The Violle standard, however, has been a veritable *ignis fatuus* for photometrists. They have been haunted by the fancy that there must be something in it to have attracted the patronage of the Congress of Electricians; and the original apparatus being unavailable, they have tried a variety of devices for throwing the light of molten or solidifying platinum upon an ordinary photometrical screen. The results have not been satisfactory, however, except as illustrations of the practical impossibility of employing light radiations from the surface of molten metal. Very much to his own satisfaction, M. Violle has demonstrated that all lights of combustion must of necessity be fluctuating and unreliable. It has been shown, however, by abundant testimony, that this objection applies even more strongly to lights of radiation from molten metallic surfaces; and so the platinum unit must be regarded as proved by the majority of witnesses to be unworthy of further consideration.

The Committee had the advantage of the use of Mr. Dibdin's testing-room and his four-way photometer at Spring Gardens—the most perfect appliance for the purpose ever used. Here they tried against each other standard candles, the pentane standard, the new pentane lamp, and the amyl-acetate lamp. They could not try any other, for the simple reason that there are no more to try. It was at one time hoped that a standard light could be obtained from an incandescent electric lamp; but this hope has faded with extended experience. Consequently, if we exclude all standards of the Methven type, produced by selecting, by means of a screen, the steadiest portion of a gas or oil-lamp flame, there are no others now available besides candles, pentane, and amyl-acetate. Between these, selection becomes comparatively easy. The candles are rejected on account of the range of their variation from the average. The amyl-acetate lamp was much more constant than the candles, but the red colour of its light, and probably also its feebleness, are against it. It will in all probability

continue to be used for some photometrical purposes, however, because of its extreme handiness and simplicity, in which it resembles a common spirit-lamp. Pentane triumphed on the score of steadiness; and is accordingly strongly recommended by the Committee, who "urge most earnestly the importance of undertaking such action as is possible to ensure the immediate rejection by the Board of Trade of the parliamentary candle as a standard of light, and the adoption of the pentane standard in all future work." They do not suggest any change in the legal name of the standard of light for the United Kingdom. It would still be the "standard candle," and the intelligible and convenient term "candle power" would be used; but the unit would not be indicated for photometrical purposes by an actual candle, for which the pentane flame would be substituted.

For gas testing, as we have repeatedly remarked, whether pentane or candles occupy the pride of place as the legal standard, the convenient, always-ready Methven unit will remain the general favourite. The British Association Committee's report does not make any mention of the Methven device; but, for all that, in their actual work with Mr. Dibdin's photometer the central light by which all the others were compared was a gas-flame with the top portion screened off. The report was not discussed at the meeting when it was presented, which is rather to be regretted, as discussion might have elicited additional information from the author, who was present, and received the customary vote of thanks. The presentation of the report closes the chapter of contemporary investigations respecting standards of light up to and including the pentane era. Henceforward pentane rules supreme as the best authorized means of representing the light of a legal candle for photometrical purposes. Something better may be suggested at a future time; but we suppose we must declare now that there is nothing so good at present known to science, and that the matter must be allowed to rest where it is until a well-accredited rival appears. There can at least be no justification for further investigations of the kind now concluded, until something new comes forward to disturb these conclusions. There can be no possible rivalry between the pentane and the Methven standards, now that their relative offices have been settled by experience, and recognized by Mr. Dibdin's report. The pentane, as used in the form of a lamp, is a portable standard, available for photometrical work where gas is not obtainable. In the photometer-room of a gas-works, or a town gas-testing station, the Methven screen, standardized by reference to the pentane flame, is convenience itself. This is the practical conclusion of the whole matter; and it is to be hoped that next time the subject of photometrical standards engages public attention, it will be with reference to some progressive action, and not to investigations and reports, of which there are now enough.

MR. CARR RESIGNS.

THE Halifax "gas scandal" has entered upon a new phase by the resignation of Mr. W. Carr, Manager of the Corporation Gas-Works, in consequence of the action of the Town Council commented upon in these columns last week. The Town Council unanimously resolved that Mr. Carr must institute proceedings against the *Pall Mall Gazette* or resign. Two months ago the Council were advised that no sufficient cause of action existed for anybody against the newspaper in question; but, notwithstanding this opinion, pronounced by their own Counsel, they sought to force Mr. Carr to commence proceedings, upon peril of losing his appointment. Mr. Carr's position in regard to the matter is very clearly set forth in the communication from his Solicitors (notifying the course taken by him under advice) to the Town Clerk, and which will be found elsewhere. It is herein stated that "notwithstanding all that was advanced in alleged justification of the course the Council were taking, our client is still advised that no action can possibly lie against the proprietors, printers, or editor of the *Pall Mall Gazette*; and therefore to commence the proceedings required by the Council is out of the question." Consequently, Mr. Carr accepts the only possible alternative, short of defying the Corporation as contemplated in our last week's notice of the affair. A sentence in his Solicitors' letter, however, reserves the right of enforcing against the Corporation "such claims as the action of the Council may enable him to make." And now, what will the Corporation do? They cannot let the matter rest where it is. They thought it would be a simple and easy way out of their troubles to make their Gas Manager a scapegoat; but now that he has preferred to sacrifice his appointment rather than undertake a task pronounced hopeless by his

and their advisers, what course remains for the Council? It seems to us they will have to go on just as though they had never thrown Mr. Carr overboard; but with the additional load of a manifest act of injustice. Once more it has been demonstrated that the simplest course out of a difficulty—by shifting it on to somebody else's shoulders—is not always the best. The more the course taken by the Town Council is looked at, the uglier it appears. According to the local newspapers of the day or two after the Council meeting at which the *ultimatum* to Mr. Carr was agreed upon, this action met with the general approval of the townspeople; and it was even reported that there was experienced in the town a feeling of relief at the imaginary prospect of something at last being done to clear off the cloud of suspicion that has rested over the Municipality ever since the publication of the *Pall Mall Gazette* innuendo. This feeling was natural under the circumstances; for most people like to know that "something is being done" in an emergency, and are not particularly curious at first as to whether the "something" is the right thing or not. In this case, however, the action of the Council has "missed fire" so completely, and Mr. Carr is so clearly in the right in the position which he has taken up, that we are inclined to imagine that by this time not a few of the doubtless well-meaning Town Councillors who agreed to the minatory resolution, regret their hasty vote. It is reported now that public opinion in the town has veered round, and is setting as strongly in Mr. Carr's favour as it did against him for the day or two after it was shown that he was deserted by the whole body of the Town Council. The fickle wind of popular applause is not to be counted, however, among the elements out of which a man's reputation is to be maintained; and we may be sure that Mr. Carr and his advisers are not under any illusion in this respect. Whatever may be hoped or feared in the town, outsiders will not refuse to listen to Messrs. Storey and Co.'s plea for suspension of judgment in the matter. Something definite is certain to come out of the maze before long. We notice in a local newspaper that Mr. Ellis Lever has deemed the business ripe for exhibiting his personality again, in his favourite character of the Patron of Purity; having come forward with another of those glittering offers of money premiums of which he is so fond—to be bestowed in this case upon the Halifax Infirmary, in the event of the vaguely-accused persons being able to clear themselves. We do not at all like giving Mr. Lever this additional "advertisement;" but the aroma of the seething Halifax "stew" would not be perfect without the Lever flavouring. Meanwhile we cannot withhold an expression of congratulation to Mr. Carr's advisers for the admirable position they have taken up in the interest of their client. His acceptance of the alternative to the impossible legal proceedings dictated by the Town Council, preserves him from antagonism to that body, and is, indeed, an expression of respect for them. At the same time it leaves them precisely where they were before, and under the same responsibility for dealing at first-hand with Mr. Fox's allegations. The Mayor has a difficult part to play. He is naturally enough reluctant to arm Mr. Fox with an indemnity; and yet he is told that nothing can be done without it. There will be plenty of interest in the development of this affair.

THE LIGHTING OF WOLVERHAMPTON.

In our last week's issue appeared a long and important report of the Special Gas Committee of the Wolverhampton Town Council relative to the lighting of the borough, which will be found worthy of attentive study by those who desire general information respecting modern systems of artificial lighting, as well as by the ratepayers of the town. The Committee took into consideration the use of oil-lamps and electricity as possible for the lighting of the borough; but the former are dismissed with very little notice and no favour. Upon the possibilities of electric lighting the report is decidedly ambiguous. It says a good deal in support of the idea that the town might be lit by electricity in competition with gas, but does not come to the point of recommending the Council to undertake such a venture on their own account; nor does it contemplate with favour the alternative of sanctioning the establishment of a local electric lighting company. This timidity on the part of the Committee is very significant. They obtained estimates from Messrs. Elwell-Parker, Limited, well-known electricians carrying on business in the town; and this firm actually went so far as to recommend the Corporation to speculate in electric lighting for the whole district, laying down for this purpose plant

for supplying 40,000 lamps, in which case they asserted that "the present price of gas in Wolverhampton could be "successfully competed with by electricity." That the Committee who obtained this information should have been content to place it upon record, without a word of recommendation, is a most significant commentary upon its practical value. It may be gathered from the report as a whole, however, that the Committee considered their principal duty to consist in investigating the affairs of the Gas Company, with a view to discovering some way of putting pressure upon the Directors to obtain concessions in the matter of price and in other respects. To this end they placed the filed accounts of the Company in the hands of Messrs. Howard Smith, Slocombe, and Co., for analysis and comparison with data furnished by other gas undertakings. Before submitting their Accountants' report to the Council, however, they showed it to the Solicitors of the Company, and obtained their explanations, which were again remitted to the Accountants for criticism. The report consequently contains, in the first place, the Accountants' statements, followed by the commentaries of the Company; and these again are capped by the Accountants. It must be admitted that the investigation did not result in the discovery of anything very damaging to the Company. Their worst offence seems to have been the payment of dividends free of income-tax; and when confronted with this impeachment, the Directors simply deny that they have been in the wrong, and declare, almost in as many words, that they mean to go on doing as they have hitherto done. As to this, it is necessary to tell them that such a position will be found untenable. Although there is nothing else of a definite character alleged against the Company, they are accused in very serious terms of grave mismanagement of their manufacturing and commercial concerns. The Committee of the Town Council believe and have persuaded the Council that the Company require to be awakened to a sense of their duty to the community whom they serve. They "feel strongly" that the period has now arrived when, in common with all "other commercial undertakings, the Gas Company should recognize the necessities of the times, and so far re-organize, if needful, the details of their business as to give the public such concessions as are possible without invading the profits upon their capital which the proprietors naturally expect." This is as much as to say that fresh blood is wanted in the administration of the affairs of the Company. In other respects the recommendations of the report are very mild.

A QUESTION OF METHOD.

So much has been published in these columns at different times on the economy of generator and regenerator furnaces, that we are very loth to begin to discuss the subject again. The point which we desire to make at present, however, is not a controversial one, but is merely a statement of an obvious truth. It is that nobody has ever yet been able to give the results of working with these furnaces in comparison with others of the same or of the older direct-acting class, in a way that satisfies everybody. If the weight of fuel required for the work of carbonization is carefully calculated out as a percentage of the weight of coal put into the retorts, somebody is certain to object that this must have been gathered from working under "test conditions," and that these cannot be expected in the ordinary way of retort-house management, year in year out. It will also be remarked that nothing is more difficult than obtaining absolutely fair returns when stokers and firemen know that their superior's desire is fixed upon securing a good showing for any experiment upon which he has set his mind. If, on the other hand, a Gas Manager eschews all test weighings, and simply declares that, whereas he once sold so much coke out of the yard before adopting a certain system of retort-setting or heating, he has since sold so much more, the statement is found fault with as unscientific and misleading. Differences in the yield of coke from various kinds of coal are "thrown at his head;" and in the end he must be a patient man if he does not sometimes repent having had the temerity to say anything about his working. This comment is not a novel one; but it bears repetition. For all that may be remarked to the contrary, we hold to the opinion that the practical "sales" test is a good one, more especially in the case of very small works. When a Manager of such an establishment is able to say, for example, that without desiring to compare his own particular fancy in retort-settings with others, to their detriment, he is able to get through the summer without buying fuel, as he once did, and even to sell a

certain quantity of his make of coke at such times, one cannot help thinking that this is ample justification for his satisfaction with his working under the new conditions, and for his publication of them for the benefit of less fortunate colleagues. In saying so much, we do not mean to deny the value of more precise tests; but we do think that the practice of complaining that when a man writes a paper, or gives results of working for what they are worth, he has not done so in some different way, can be pushed to such an extreme as to deter others from contributing useful information. If errors are committed, or bad faith suspected, by all means let right be done by valid criticism. We offer these remarks not with any view to personal applications, new or old, but purely in the interests of future writers of technical papers, and of Secretaries of Associations in difficulties with respect to the elicitation of such communications from authors who may have a plain story to tell, but do not like the idea of being dragged into controversies respecting their manner of telling it.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 521.)

BUSINESS on the Stock Exchange was again very active all last week; and the settlement was a heavy one. The tendency of almost all descriptions has been upward, with the exception of American Rails; the failure of one of the chief granger lines to earn even its preference dividend for the last bad half year being a serious blow. The Bank of England rate was raised on Thursday from 3 per cent. (at which it had stood for five weeks) to 4 per cent. It was only last week that we wrote anticipating that the rate would remain unvaried; but we have nothing to retract, for the change was a general surprise. Business in the Gas department has been on the whole only moderate, although a few issues have been more than usually active. The changes in the quotations are somewhat irregular and capricious. South Metropolitan "A" and Commercial old have been lowered; the former 2, and the latter 1. But at the same time, not a single transaction has been marked in either of them. South Metropolitan "A" now figures to return $\frac{1}{2}$ per cent. more for money than the "B;" but we do not know why. Gaslight "A" has been extremely steady all the week, at about 255; all transactions marked ranging no more than a fraction higher or lower. The demand for debenture and secured issues has been much quieter. Imperial Continental has risen 1; having changed hands repeatedly at 210 $\frac{1}{2}$. In Continental Unions, the fully-paid shares are put down $\frac{1}{2}$, and the partly paid put up $\frac{1}{2}$, which brings them more nearly together in point of value. The only other change is a rise of 1 in Buenos Ayres debentures. Water was quiet and very firm during the earlier portion of the week; and several issues made considerable further advances. But towards the close there was some disposition to realize. For the last two or three months, the stocks have been steadily rising; and a good profit can be made out of them at present figures.

The daily operations were: On Monday, the business in Gas was very restricted, and offered no feature of note. South Metropolitan "A" receded 2; but Imperial Continental advanced 1. Nothing at all was done in Water. Tuesday's Gas business was mainly in foreign undertakings; the home companies being scarcely dealt in at all. Buenos Ayres debentures rose 1; and Continental Union, partly paid, $\frac{1}{2}$. But Commercial old fell 1. In Water, Chelsea advanced 2; and Lambeth and Southwark ordinary, 1 each. There was no increase in activity in the Gas department on Wednesday; and all prices remained unchanged. Water was a shade busier; and Chelsea rose 2 more. New River debentures also improved 1. Thursday's business in Gas was only moderate, and prices were but fair. Continental Union, fully paid, receded $\frac{1}{2}$. Water was about the same. Lambeth advanced 1 more, and was marked at top price. Southwark ordinary rose 2. On Friday, business in Gas was much the same as the previous day, and prices remained at the same level. Water was extremely active, and a good many issues changed hands; but the figures were mostly low. On Saturday there was a little done in Gas at fair prices; but Water was an absolute blank. All quotations remained without further change.

ELECTRIC LIGHTING MEMORANDA.

PROFESSOR AYRTON ON THE ELECTRICAL TRANSMISSION OF POWER—A TOTAL ECLIPSE AT BARNET—RIVALRY AT LEAMINGTON—A PANEGYRIC ON ELECTRICITY—THE LIGHTING OF THE MANCHESTER EXHIBITION LAST YEAR.

THE popular lecture which is always a feature of the British Association meetings was this year delivered by Professor Ayrton; the subject being the "Electrical Transmission of Power." The lecture (of which an abstract appears elsewhere) was very popular, for there is nothing like electricity for amusing an audience; and Professor Ayrton is a very able expositor. He knows exactly the sort of explanations and experiments that will interest a popular audience; and he gave plenty of the latter at Bath. With regard to the subject which furnished a title for his lecture, the learned Professor did not say very much that was new. He claimed for electrical distribution of power economy of fuel, more perfect control over each individual machine, ability to bring the tool to the

work instead of requiring the work to be brought to the tool, greater cleanliness, and, lastly, the advantage that the power which during the daytime is used for driving machinery can be used during the night for giving light. These claims suggest some reflection. The Professor did not explain how it is that the electrical distribution of power, which he said was so economical of coal, is so expensive in money. He did little more than hint at M. Deprez's disastrous experiments in this line, which were too much even for the Paris Rothschilds. He could not explain why the gas-engine and the hydraulic motor are so popular in London and other great centres, while electric-motors, at least as old as the latter, are so rarely heard of. And, with regard to his last claim, what does it mean, except that all work with electro-motors must cease at dusk? This may be a desirable result from the humanitarian standpoint; but it was not precisely from this point of view that Professor Ayrton was recommending electrical distribution. On the whole, the lecture may be fairly described as brilliant; but it left the subject pretty much as it was, ending, as it began, with a display of electrical fire-works. Professor Ayrton would scarcely like to be told that the Bath public enjoyed his display much as though it had been an indoor copy of Brock's or Pain's pyrotechny; but such a rendering would not be far from the truth.

Poor Barnet! Only a week ago it was proclaimed in a score of newspapers as being the most enterprising little town in the kingdom, on account of the Local Board having taken up with electric lighting for the streets; and now the inevitable extinction has come already. "Owing to an unfortunate accident," as one of the newspapers remarks, "the electric light which was installed with success at Barnet a fortnight ago suddenly collapsed on Wednesday night, and the town was left in total darkness for some hours." The old story. Of course, the system was not to blame. It was only a new and improved dynamo that struck work at an inconvenient time, on account of the overheating of a bearing. Still, notwithstanding all the pains of the electrical contractor and his newspaper apologists, the interesting fact remains that he plunged Barnet, that "go-ahead town," in total darkness for several hours. We have no desire to unduly magnify this awkward episode, which, if it had been the only one of its kind, might have escaped notice. Seeing how persistently electric lighting machinery disappoints its patrons at awkward times, however, one is bound to notice its return to its old tricks, even when tried in new places.

There is a fresh development of the electric lighting question at Leamington. A London firm have written to the Corporation offering to introduce into the town what is called the "Waterhouse" system of electric lighting, apparently in competition with the local Chamberlain and Hookham Company. We do not know what this particular system of electric lighting may be. Westinghouse we know; but who is or what is Waterhouse? However, the dazzling prospect is held out to Leamington that if the Corporation will favour this particular system, the town will "stand on a par with Berlin and other cities on the Continent." The style of the letter does not give a reader any very high opinion of the writers; but this is perhaps mere prejudice. There is a grand vagueness about the project also, for beyond remarking that "the most successful manner of lighting is to use arc lamps for street lighting, and 50 or 100 candle power incandescent lamps for shop lighting, and 16-candle power lamps for domestic purposes," the promoters say nothing to indicate what their system is. Still less do they show concerning its cost, for there is not a single reference or hint of the money side of the question, which is gracefully kept in the background. Very little notice was taken of the offer of this public-spirited London firm. It was perhaps considered that it would have looked better if they had directed their attention in the first place to other towns where there would not have been the suspicion of rivalry with other electricians struggling to make a paying business under unfavourable conditions.

Mr. John Stent has published a little book entitled "Electricity versus Gas," "as a small contribution to aid in extending the knowledge of electric lighting in this country, and to promote intelligent confidence in electricity as the certain illuminant of the future, for the whole world." If one asks who is Mr. Stent, that he should come forward at this time of day in his self-appointed character of "promoter" of electrical knowledge, the answer is not easily forthcoming. The book is a long panegyric of electricity and disparagement of gas, but with what object it has been written and published remains a mystery. It is conspicuously, even painfully vague. There is not one reference in its feeble pages to any particular system, so that it is scarcely an advertisement; while the eulogistic tone of every reference to electric machines, lamps, &c., removes it from the rank of purely scientific and technical manuals. Indeed, it is the perfection of commonplace writing; for there is little use made anywhere of figures, and there is not a statement in the whole book which conveys any fresh information, or discloses a new view of its subject to a reader of ordinary intelligence and scientific training. Why are such books written? It is a question more easily put than answered. Mr. Stent asks sixpence for his book; but we cannot truthfully say that it contains sixpennyworth of information for anybody. It is not a work that one can usefully quote from; but we cannot resist the temptation of giving one passage from the author's peroration. "In discovering and applying electricity to the service of man," he exclaims in a fine phrensy, "we have found the heir to the sun, and his regent whom his rule is suspended. In electricity we have reached an ultimate beyond which there is no successor. The work of the savants of our time is to enable the historian of

this nineteenth century to say: 'Within the last quarter of the century electricity became the common light of the United Kingdom, and of all the civilized nations of the earth.' Therefore, why should people be afraid to risk their money in electric lighting speculations?"

The report of the Executive Committee of the Manchester Royal Jubilee Exhibition—preliminary copies of which were issued to the press last week—contains some particulars of interest in relation to the electric lighting of the building and grounds. As the Committee remark, the installation was one of the largest yet erected in this country; and its cost was on an equally liberal scale. The cost to the Committee was no less than £10,238 12s. 4d. For this sum they had in actual use 512 arc and 3570 incandescent lamps; the former being in use for 556, and the latter for 560 hours. Roughly, therefore, the lighting by electricity cost the Committee rather less than £20 an hour. This was not, however, the sole cost; for it does not include the extra lamps which exhibitors contracted for, to light their own special exhibits and add to the attractiveness of their individual parts of the show. Nor was the electric light the sole illuminating agency employed. Throughout the machinery section and some of the other departments, gas was extensively used; while in the grounds there were no fewer than 10,000 various coloured oil-lamps. With reference to the installation, it appears that tenders were invited from all the leading firms of electrical engineers; and, after considering them, the Committee accepted that of the Anglo-American Brush Electric Light Corporation for the arc lights, and that of the Manchester Edison Swan Company for the incandescent lamps. The actual number of arc lights contracted for was 546; and these were arranged in 24 circuits. But one of the circuits was afterwards cut out, and the number of lights reduced to the 512 already mentioned. They were to be in use 600 hours; but they were actually employed for only 556. The incandescent lights were used in the art galleries and for other internal lighting; and they were in use for 560 out of the 600 hours. During the whole of the time, say the Committee, no electrical failures occurred; and the lighting was extremely satisfactory. All which goes to prove that the Manchester people were extremely fortunate; and that, where cost is not a matter for serious consideration, good results may be achieved by electrical engineers.

THE LAWRENCE GAS AND OTHER SIMILAR SCHEMES.

THE time of competitive proprietary gas schemes has come again, just as though electric lights were a dream of the night. As we glance through our piles of technical journals published at home and abroad, we here and there stumble upon announcements that recall the palmy days of Dr. Eveleigh and the New Gas Company. The "fatal facility" with which a luminous aëri-form fluid can be prepared by passing air, or a combustible but non-luminous gas, through volatile mineral oils and spirits is at the present day a source of as much delusion among men as it ever was; so that scarcely a month passes without bringing its newspaper declaration that Mr. Brown, Mr. Jones, or Mr. Robinson has succeeded in inventing a wonderful gas which is called by his name, but which the dispassionate observer finds, upon the most superficial investigation, to be nothing more than a mixture born in a carburettor of more or less fantastic design. Last February we had occasion to publish in these columns a warning upon the subject of the then newest of these proprietary gases, which was being advertised in London under the name of the Lawrence "Patent Automatic" gas. We explained how advantage was taken of the supreme ignorance of the average reporter of everything connected with gas, to foist this patent "gas" upon the public as something altogether new and deserving of attention; and in short did our best to prick the bubble that a mere handful of sharp City men were trying to blow out of the stale soapbuds provided by a probably cunning, but certainly uninstructed Yankee "inventor." We did not succeed in putting a stop to the progress of this Lawrence gas speculation; for at the present time it appears to be in full swing. Large consumers of gas in London are being canvassed by the agents of the Lawrence Gas Company for permission to establish the machines of the Company upon their premises. We have before us a printed form of agreement which consumers are asked to sign; and must admit that it does not contain anything objectionable. It is in the form of a requisition addressed to the Company for one of their machines, to be fixed, free of cost in any event, upon the consumer's premises. In consideration of this service, the subscriber agrees to pay to the Company "one-half of the amount saved to us in our gas bills, after deducting from the total amount saved the cost of the material furnished by you to the machine; said amount of saving to be determined by a comparison with bills for gas of twelve months previous to the setting of your machine, due reference also being had to the number of burners used." By way of inducement to fall in with this enticing arrangement, the prospective client of the Lawrence Gas Company is favoured with copies of reports upon the so-called gas from a Mr. Adolphe M. Levy, who signs himself "civil engineer," and from no less a personage than Dr. John Hopkinson, F.R.S., dated June 1 last.

As for Mr. Levy, he is not worth much notice; and it would be useless to sift all his elaborate calculations, whereby it is shown that, to carburet common coal gas with gasoline results in a saving of between 45 and 50 per cent. to the consumer. Dr. Hopkinson, however, is another kind of person. He has been regarded as a scientific Engineer of the highest standing; and when such a man proffers a report upon a gas-lighting device, it is but giving him his due to

take some notice of what he has to say. Dr. John Hopkinson, C.E., F.R.S., &c., &c., is doubtless a witness who should be respected. He has for several years past laid himself out for that particular class of business which consists in reporting upon patented devices, and giving expert evidence in patent-law cases. He hunts, if we may be allowed the expression, with Sir Frederick Bramwell, Mr. Imray, and their like; and he probably finds the pursuit very profitable. We are prepared to admit the necessity for such men—which is going a long way—and to honour them when they succeed in the delicate task of combining a reputation for honesty with the requisite commercial faculty of viewing a question largely according to their instructions. When, however, one of them, purely as a matter of business, reports upon such a very peculiar article as the Lawrence "gas-economizer," it is time to inquire somewhat particularly how, in such a case, the expert manages to preserve the combination already mentioned, upon which his value as a witness depends. Regarded from this standpoint, Dr. Hopkinson's report upon the Lawrence gas is painful reading, since it inspires one with the opinion that no professor of science can do himself credit by dabbling in these matters. People will very soon learn what to think of Dr. Hopkinson if he continues to father such statements as the one which we have before us, and which is nothing more than an artfully-worded warranty of a special commodity, just as valuable, or the contrary, as those analysts' certificates which are advertised in recommendation of pickles and sauces, and depending for its marketable value solely upon the writer's name and position in the world of science.

To begin with, then, Dr. Hopkinson's report professes to be upon something called the Lawrence gas-economizer—that is, upon some special kind of apparatus. It appears from the body of the report, however, that the photometrical observations upon which the chief conclusions relating to the value of the Lawrence appliances are based, were made upon gas carburetted in a mere box of trays containing shavings steeped in gasoline—that is to say, upon the effect of carburetting gas with gasoline; for nobody can pretend that there is anything special in such an apparatus as was employed in this instance. The question arises, What is this Lawrence "economizer" which Dr. Hopkinson was called in to examine and expected to recommend? In his own words, it is an apparatus "intended to enrich gas by passing the gas over wood shavings soaked in gasoline. The gas evaporates a portion of the gasoline in passing over it, and becomes enriched thereby. No external heat is applied to the chamber in which the gasoline is contained; and in this respect, *so far as I know*, the apparatus differs from previous apparatus of the same kind." When Alice was having those remarkable colloquies with the very outspoken creatures whom she met in Wonderland, she remarked to the Duchess that she did not know any cats that grinned; and the Duchess very promptly and pertinently replied, "You don't know much; that's a fact." Dare one say the same with regard to the position of such a truly authoritative personage as Dr. John Hopkinson, F.R.S., &c., with relation to gas-carbureters? Why, carburetting gas is a notion as old as gas making. Innumerable forms and varieties of carbureters have been tried at one time or another during the last half-century; and by far the great majority have not depended on external heat. If Dr. Hopkinson does not know this, he should not have said anything on the subject.

When he comes to photometrical tests, Dr. Hopkinson sinks his own individuality, and becomes merely the mouthpiece of the Lawrence gas people. Thus, he talks of a No. 0 Bray's union-jet burner as a "standard" for Lawrence gas; and, for comparison, places its duty with the common coal gas supplied to the City of London (which by the way, he prices at 3s. per 1000 cubic feet) beside that which it gives with freshly-carburetted Lawrence gas—this latter being produced by passing the former through shavings soaked in fresh petroleum spirit, of specific gravity 0.638, placed in a box on the gas-pipe a few feet from the photometer. If, according to the old truism, figures can be made to prove anything, so can photometry when suitably "worked." This photometrical exercise of Dr. Hopkinson's, conducted "by the desire of the Directors of the Lawrence Light, Heat, and Power Company, of London, Limited"—and apparently according to principles prescribed by them—is simply a parody upon the photometry of gas. Dr. Hopkinson's deliberately-expressed conclusion upon the whole matter is "that with Lawrence gas made in the small apparatus, whether jacketed or unjacketed, compared with City gas burned at equal power in good burners, the use of the Lawrence gas effects a material economy." Upon this we make bold to declare that the conclusion thus formally stated is not borne out by the data given in the report, which are wholly inadequate, and not proper for the support of any such opinion. By the way, Dr. Hopkinson has nothing to say about the asserted "automatic" character of the Lawrence apparatus. The report is as hollow and worthless as the project it is made to advertise. "There is nothing in the Lawrence so-called 'economizer' to distinguish it from thousands of other similar devices that have long since been forgotten. It is no better than a thing that any gasfitter is at liberty to make and supply to anybody. There is nothing new in the idea of enriching gas with the vapour of gasoline; and there is nothing to be gained by it, because, although the illuminating power of the gas so treated can be raised threefold, it costs thrice as much as the uncarburetted gas, to say nothing of the trouble, danger, and annoyance of the process." Such is our "report" upon this Lawrence gas—economizer and all; and we challenge any gas engineer who knows the facts to say whether this statement is not nearer the truth than that of Dr. Hopkinson.

Mr. Lawrence must look to his laurels, however, for he is not alone in the field. Lately an individual evidently hailing also from the great Republic where gas comes naturally out of the ground, came to the office of the JOURNAL with a mysterious parcel under his arm, and expressed a desire to give a display of a "new system of lighting." The parcel when unpacked proved to be a suspicious-looking copper box, to which were fixed an india-rubber tube and a brass pipe terminating in a gas-burner. With a most impressive air, the proud inventor displayed his treasure, the result, as he declared, of long years of labour and study. "Now, Sir, I will show you the result," he said—and the man, putting the end of the india-rubber pipe to his mouth, solemnly began to blow into the box while he struck a match and lit the carburetted air as it issued from the gas-burner. Then, allowing the flame to die quite out, he waited smilingly for the exclamations of astonishment and delight which he seemed to expect from his small but interested audience. There was silence for awhile; and then someone ventured to ask "Is that all you have to show us?" The poor man's self-satisfaction gave place to amazement, and this speedily passed into rage. He tried, in a slow torrent of indignant explanation, to maintain the greatness of his discovery; but ultimately retired, probably in hopes of finding a more appreciative auditory elsewhere. And in a recent issue of the *American Manufacturer* we find a very cloudy and indifferently-written account of a wonderful invention of the same kind, whereby a Mr. Johnston, "who was one of the pioneers of water gas," after 30 years' experience, has succeeded in making a "gas" containing 97 per cent. of air and 3 per cent. of petroleum vapour, which is cheaper than natural gas for every imaginable purpose. There is no difficulty in making the "gas," since the process consists in forcing air by means of a pump through a row of vertical "converters" containing petroleum; the air from the top of one vessel being taken to the bottom of the other, and so on—one of them being heated by a hot-water jacket. Crude oil is used; and, according to the published reports, "the average cost of the heating gas, where reasonable quantities are produced, will be 2 cents per 1000 cubic feet. The illuminating gas under similar conditions will cost 4 cents per 1000 cubic feet." Where is Lawrence gas now? It will be nowhere in the race when Mr. Johnston comes over from Pittsburgh to look for the necessary capitalist in Fenchurch Avenue or thereabouts.

Seriously, however, all this goes to show that there is yet an astonishing reserve of ignorance and credulity in the world with respect to gas matters, which affords a splendid opportunity for self-delusive schemers to establish their footing among a certain class of financiers. Then, when some money has been embarked upon the project, in ignorance or defiance of the experience of others who have gone before, there is no difficulty in procuring the services of experts, with any number of letters after their names, to report favourably upon just so much of this "system" as they are paid to see. This is all a part of that modern science and material progress which we have heard so much about during the last week or so in connection with the meeting of the British Association; but it is an aspect of it to which optimistic newspaper writers and readers do not usually pay sufficient attention.

AMONG the money grants submitted to the General Committee of the British Association for approval at their recent meeting, was one of £100 for investigating the subject of electrical standards.

THE death is announced of Mr. Peter Griess, whose name will be familiar to many of our readers as one of the discoverers of coal-tar colours. The deceased gentleman, who was staying at Bournemouth, passed away suddenly and unexpectedly.

IN order to test the liability of the Company for the results of the accident, one of the men injured by the explosion that occurred in May last in the gasholder house of the Montreal Gas-Works (as reported in the JOURNAL at the time), has brought an action to recover \$1200 as compensation.

THE *Japan Daily Mail* for the 25th of July last contained a short notice of the meeting of the Tokio Gas Company, Limited (of which Mr. W. Newbigging, son of Mr. T. Newbigging, C.E., of Manchester, is the Engineer and Manager), which was held on the 22nd of that month. A report on the general business and financial position of the undertaking in the first half of the present year was submitted; and a dividend for the six months, at the rate of 10 per cent. per annum, was declared.

THE appointment of Mr. Irving to the position of Resident Engineer of the Stapleton Road works of the Bristol United Gaslight Company was intimated in these columns last week; and we now learn from the Secretary of the Company (Mr. J. V. Green) that the Board have selected Mr. E. J. Lloyd for the similar position at the Avon Street works. Mr. Lloyd was formerly Manager of the Dudley Gas-Works; but is at present Gas Engineer at the York Street works of the Leeds Corporation.

THE *Engineer and Iron Trades' Advertiser* describes a method of removing rust from iron by immersing the articles in a bath consisting of a nearly saturated solution of chloride of tin. The length of time during which the objects are allowed to remain in the bath depends on the thickness of the coating of rust; but in ordinary cases twelve to twenty-four hours are sufficient. The solution ought not to contain a great excess of acid if the iron itself is not to be attacked. On taking them from the bath, the articles are rinsed in water and afterwards in ammonia. The iron, when thus treated, has the appearance of dull silver; but a simple polishing will give it its normal appearance.

Notes.

PETROLEUM AND NAPHTHA ENGINES.

Messrs. A. Shirlaw and Co., of Birmingham, the makers of the Spiel petroleum-engine, have issued a statement comparing the performance of their engine, which works with petroleum or shale spirit, with that of an engine using common petroleum. Although the engine selected for comparison is not named, it is evidently the Priestman petroleum engine, for which so much has recently been claimed. It is stated that, although the Spiel motor uses by preference naphtha or shale spirit which can be readily obtained at $7\frac{1}{2}$ d. per gallon, it will work with petroleum. The supposed danger of employing naphtha is said to be exaggerated, since the Fire Insurance Companies do not make any extra rate where the Spiel engines are employed. With regard to the comparative working of the engines, it appears that the motor using common petroleum made 160 revolutions per minute; developing 6.43-horse power on the brake, and consuming 1.71 pints of oil per brake horse power per hour. The cost per brake horse power per hour is given as 1.389d.; the figures being taken from a report by Sir William Thomson, and referring to an engine with a cylinder 10 inches diameter and 15-inch stroke. With the Spiel naphtha motor, it seems that 14 brake horse power were developed with a speed of 160 revolutions per minute, from an engine with a cylinder $9\frac{1}{2}$ inches diameter and 18-inch stroke; consuming 0.90 pint of naphtha per brake horse power per hour, and costing 0.843d. per horse power, with spirit at $7\frac{1}{2}$ d. per gallon. In reply to this comparison, the makers of the Priestman engine remark (in effect) that it is easy to get striking results from a naphtha-engine; and that they waited two years before putting their engine upon the market, in order that they could recommend it as capable of working with common petroleum oil such as can be bought anywhere by the barrel, instead of depending upon the use of volatile spirit. It is evident, however, that the supremacy of the gas-engine as a convenient source of power is being contested on all sides; and these figures are published here to show what is claimed by the makers of oil and spirit motors.

A TESTING MACHINE FOR ROAD METALLING.

The durability of road metalling and paving material is a question that cannot be settled by reference to the tensile or crushing strength of the substances used. Mr. W. F. Stock, the Public Analyst for the county of Durham and the borough of West Hartlepool, has therefore devised a method of testing stones intended for pavements; and it is described in a recent issue of the *Engineer*. The author remarks that what is wanted is a quick test, whereby the value of a quarry or consignment of stone for road making may be ascertained. Mr. Stock recommends that in such cases the stone should be analyzed, in order to determine the probability of its destruction by oxygen and carbonic acid. The specific gravity is to be determined, to give the covering capacity. The porosity of the stone largely indicates its power of resisting frost. No tests of tensile or crushing strengths are regarded by the author as of any practical value. What is wanted, he argues, is to know the capability of the material for resisting the action of light blows combined with abrasion. To effect this he has constructed a machine consisting of a cast-iron cylinder, to contain the material required to be tested, mounted by trunnions upon a frame, on which it is capable of being revolved in a longitudinal direction. The cylinder is 12 inches long, and 6 inches diameter, closed by blank flanges at each end. A stud on the axle actuates a revolution counter indicating up to 100,000. The rock to be tested is worked into inch cubes with smooth finished faces. Nine of these cubes are dried in a water-oven for two hours, and then carefully weighed and placed in the cylinder of the test machine with nine cubes of hardened steel of 0.8 inch face. A number of these steel tubes should be procured at one time, all forged and hardened to their best. Their faces must be smoothed; their angles sharp; and they should be hard enough to scratch crown glass easily. Forty ounces of distilled water are now added to the contents of the cylinder, which is then closed and revolved through 3520 turns (or two miles of travel for the cylinder), at a uniform speed of 40 revolutions per minute. At the end of the run, the stones are removed, washed in distilled water, dried again in the water-oven, and reweighed to ascertain the loss. The result shows that granites may lose from 7 to 8 per cent.; while a quartzose slate will lose 12 per cent. by weight. A standard may thus easily be set up for the stones available in any district. A machine of this kind might be found useful for other purposes besides testing road metal.

THE STRENGTH OF CEMENT.

Mr. Walter S. Church, one of the Assistant Engineers of the New Croton Aqueduct, for the supply of water to the City of New York, has published, in graphic form, the results of the official tests of all the cements used in this work up to July last. Great quantities of cement of many different brands have been employed. The records of 55 brands of Portland cements show higher breaking strains, and a more rapid increase of tensile strength up to an age of nine months, than the native American cements with which they are compared. Their average reaches 711 lbs. per square inch at nine months. A great feature of the diagrams is the effect of the admixture of sand in lowering the tensile strength. Mortars gauged as one of cement to one of sand only showed an average strength of 398 lbs. at the end of six months, as against 663 lbs. per

square inch with the neat cement. The quality of the workmanship in the New Croton Aqueduct has been tested in an unusual manner by the piercing of holes through the masonry at different points, at intervals of one and two years after its completion, in search of defects in the quality of the mortar, workmanship, &c. As a whole, the result has been found to be satisfactory. The careful tests which were insisted upon with regard to the cement frequently caused the rejection of large lots of the material, both native and foreign. The American brands, as a rule, attained a tensile strength of 123 lbs. per square inch during the first week, and gained 177 lbs. per square inch during the next two months; after which the gain of strength is much slower. At the end of eighteen months, they reach 401 lbs.; and at the close of two years, 424 lbs. per square inch. It thus appears that good native American cements, used neat, are about equal in strength to average Portland cement mortars when gauged as one of cement to one of sand.

A CHEAP NON-CONDUCTING PREPARATION FOR STEAM-PIPES.

A non-conducting coating for steam-pipes, &c., used for the past ten years with perfect satisfaction by a Boulogne engineering firm, is described in a recent issue of the *Revue Industrielle* as being conveniently applied and cheap; while it can be prepared by any steam user. It consists of a mixture of wood sawdust with common starch, used in a state of thick paste. If the surfaces to be covered are well cleaned from all trace of grease, the adherence of the paste is perfect for either cast or wrought iron; and a thickness of 25 mm. will produce the same effect as that of the most costly non-conductors. For copper pipes there should be used a priming coat or two of potter's clay, mixed thin with water and laid on with a brush. The sawdust is sifted to remove too large pieces, and mixed with very thin starch. A mixture of two-thirds of wheat starch with one-third of rye starch is the best for this purpose. It is the common practice to wind string spirally round the pipes to be treated, keeping the spirals 1 centimetre apart, to secure adhesion for the first coat, which is about 5 mm. thick. When this is set, a second and third coat are successively applied; and so on until the required thickness is attained. When it is all dry, two or three coats of coal tar, applied with a brush, protect it from the weather. It is stated that 20 frs. worth of starch will go as far in this way as 1000 frs. spent in any known commercial non-conductors of heat.

THE COMPOSITION OF CEMENT PAVEMENTS.

Although cement is frequently employed in the composition of floorings or pavements intended to resist the wear and tear produced by the friction of feet or wheeled vehicles, there is very little information available respecting the resisting qualities for this purpose of different mixtures. It appears, remarks the *Moniteur de la Céramique*, that resistance to wear upon the surface does not greatly depend upon the resistance of the cement to rupture or breaking as determined by the usual methods. In other words, it is not necessarily the most tenacious cement which is also the hardest. The nature and quality of the sand are equally influential in controlling the result; but if a series of tests is made with the same sand, upon a great number of different cements, the particular effect of the sand itself will be eliminated, and the resistance of the cement will alone remain to be considered. M. Bohme has accordingly endeavoured to ascertain, upon this principle, what is the precise proportion of cement to sand that gives the best results, regarded as a paving material. The data which he has obtained from the comparison of 23 different agglomerants go to show that this proportion varies, according to the nature of the agglomerant, from 1 to 1, to 1 to 2. In the majority of cases, the best mixture will be found to be 1 of cement to $1\frac{1}{2}$ of sand. Such is the proportion which will give certain satisfaction in the case of a cement the properties of which have not been specially studied. This resistance to friction of pure cement is in the mean the same as that of a mortar composed of 1 of cement to 3.5 of sand. The comparative equality of strength, however, is not the same for different mixtures. Indeed, it may be said to vary through a wide range. In instances cited by M. Bohme, it was as the minimum 1 to 2, and as the maximum 1 to 5.

The Committee recently appointed by the Paris Board of Health to inquire into the dietetic properties of saccharine have expressed the opinion that it should be debarred from use in articles of general consumption, as being prejudicial to public health. Its use in brewing has, it will be remembered, already been prohibited in the United Kingdom.

The people of Pittsburgh, who have of late years been congratulating themselves on having a cheap and cleanly fuel in natural gas, are now regarding it as a not unmixed blessing; for the natural gas corporations have combined and raised the price of the fuel above that of coal, and one institution (the Dixmont Hospital) has been compelled to return to the use of coal.

HERR HEMPEL states that liquids can be evaporated about six times more rapidly (with, however, the combustion of about three times the amount of gas per hour) than on a steam-bath, by employing a Siemens inverted regenerative burner placed just above the surface. The liquids do not enter into ebullition; so all spitting is avoided. Experiments show that no appreciable amount of sulphuric acid is absorbed by the liquids during evaporation; and that, whilst hot, the iron parts of the burner are not attacked by acid vapours.

Technical Record.

GADD'S SPIRAL-FRAMED GASHOLDER.

As intimated in our "Correspondence" columns to-day, Mr. W. Gadd, of Manchester, has filed the complete specification of his patent for spiral-framed gasholders; and as it has now been accepted by the Patent Office authorities, we are enabled (by the courtesy of the inventor) to publish a description of the proposed arrangements in Mr. Gadd's own words.

According to the specification, then, the improvements relate to the construction of gasholders; and have for their object the supporting of the same, in their working position, in such a manner as to enable the external or upper guide-framing hitherto employed for the purpose to be dispensed with, and yet to give the requisite stability, although such, or a modified form of framing, may be employed in connection with the improvements when desired.

To accomplish this and to effect my improvements (says the patentee), I form the interior of the tank or well in which a holder for the containing of gas is allowed to rise and fall, in a special and peculiar manner—that is to say, affixed to, or let into the face of the tank or well, or forming part thereof, or in recesses therein for the purpose; and extending from top to bottom thereof or thereabouts, are rails of metal or other suitable substance, or it may be recesses or grooves, which are formed in the shape of quick helices or spirals, or curved inclines, and (by preference) making in their total length one-quarter turn of the circle, when the holder employed is very high and telescopic. But a quicker or slower helix, or spiral, or incline may be adopted, according to the circumstances and design of the same, and which will be determined by the angle of inclination adopted; 45° and 60° from the horizontal being examples of working angles, but other angles may be employed. Arranged at intervals around the circumference of the holder, close to the bottom edge thereof, or at such distance therefrom as is desirable, and coinciding with, or fitting on to the helical or spiral rails or curved inclines attached to or forming part of the tank aforesaid, are flanged or other wheels, or anti-friction rollers, of any suitable size or form, which are made to run loosely, by preference, and may be free to slide to a certain extent laterally upon their respective axles, to allow for expansion or contraction of the holder. Or blocks or sliding-pieces or equivalent devices may be employed in lieu of wheels or rollers, or both may be combined, and the flanges may be on either or both edges. As these flanged or other wheels, rollers, or blocks, or equivalent devices, rest and move upon the helical or spiral rails or curved inclines before mentioned, by preference both over and under, or between, it will be seen that, as the holder becomes raised by being filled with gas, a screw-like motion is imparted to it—causing it to partially turn as it rises, and, in similar manner, allowing it to fall by gravity as the volume of gas is reduced.

The stability of the holder lies in the fact that it is constantly, at all working heights, supported at its base or lower edge or ring; and thus presents a position of firm resistance to wind pressure and other lateral strains, under conditions somewhat similar to that of a holder placed on the ground upon its lower edge or rim.

The flanged or other wheels, rollers, sliding-blocks, or equivalent devices may either be fixed tangentially with the side of the holder, and so run upon the top, or top and bottom surfaces of the rails; or they may be arranged radially with the holder, but at the angle of spiral. Or (and by preference) the two kinds may be combined, and the rolling surface of the rails adapted thereto, or in any other suitable manner; and the rollers, or sliding-pieces, or equivalent devices, when placed tangentially, may be employed above and beneath the rails alternately, or in couples or otherwise—the rails being constructed in double line, or double-headed or faced for the purpose.

The improvements are also applicable to telescopic gasholders, by employing similar helical or spiral rails, curved inclines, or grooves, within and attached to the lower or outer lift or lifts thereof, upon or within which the rollers or equivalent devices attached to the inner lift may work or move.

As a modification of the invention, the helical or spiral rails, grooves, or inclines may be employed upon a framing or cylinder within the lower or outer lift or holder itself; the wheels, rollers, or equivalents being affixed to the inner wall or face of the holder or lower lift. Or the holder or inner lift or lifts may all or in part be reversed in their arrangements of helical, spiral, or inclined rails or grooves, and their wheels or rollers; so that the latter are affixed to the tank and outer lift or lifts, or in connection therewith, while the rails, inclines, or grooves are fixed to, or form part of the holder or inner lift or lifts.

Fig. 1 represents an elevation, with half plan of a single-lift gasholder, raised to about its full height (and with the tank or well shown in section), of one arrangement in accordance with this invention; and figs. 2 to 8 show examples of some variations of detail in the application of the method described.

A is the holder; and B the tank or well, within which the holder rises and falls—riding on the helical, spiral, or inclined rails or surfaces E. C are the tangential, and D the angled radial rollers, which in fig. 1 are shown arranged separately from, and alternately with the tangential rollers C. By such an arrangement, they may either roll on the face of the tank or well, or upon plates or rails placed at the required angle or spiral thereon. But the two kinds of rollers may be arranged together, as shown in fig. 2, wherein the rail may be formed of channel or other iron, having a tangential roller on each side, with the angled

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 7.

radial roller between. Or the angled radial rollers may be dispensed with by employing flanges on the tangential rollers; or other means may be employed for keeping the holder centrally, or the wheels thereof on the rails.

In the interests of safety, the patentee greatly prefers to employ either two sets of rollers—one above, and the other below the inclined or spiral rails—or double rails with one or more sets of rollers between, in order to enable the same to securely grasp, or to be grasped by the rails at various points around the edge of the holder; but nevertheless it may be possible, in some cases, to dispense with the under-set of rollers, or the over-set of rails, as the weight of the holder may be sufficient to cause the rollers to follow the inclines of the rails.

In fig. 3, the two sets of rollers are placed one below the other, instead of in line; and one of them is shown flanged. In fig. 4, two rails to each roller are shown, or it may be an inclined recess in the tank or well face, by which variation the locking action or grasp is obtained by one set of rollers. Figs. 5 and 6 show two forms of sliding blocks or pieces, which may be employed in lieu of rollers, and either in conjunction or not with the angled radial rollers. To enable allowance to be made for imperfections in the construction of the helical, spiral, or inclined rails, or for the effects of expansion or contraction therein, the studs attached to the curb or ring of the holder, carrying the tangential rollers, may be arranged to have radial play within the central boss on which the rollers turn, as shown in fig. 7, in which the tangential roller C turns on the boss C¹, having formed therein the slot C² to enable the projection or stud A¹, attached to the ring of the holder, to pass through; or other devices for radial action may be employed. A similar arrangement is shown for the sliding-pieces in figs. 5 and 6.

Fig. 8 (see next page) is a part section showing the application of the invention to a telescopic holder, wherein the outer or lower lift is provided with rails in manner similar to the tank or well, for the

FIG. 8.

purpose of allowing the inner lift to rise and fall thereon. In like manner, a third lift may be employed, or more.

Further variations in detail may be made, and modifications of the invention may be effected, by attaching the rails to the holders, and placing the rollers around the edge of the tank or well, whereby the entire arrangement is reversed; or combinations of the two methods may be employed. Also the invention may be turned about, so to speak, by affixing the curved rails to a framing placed within the tank, but inside the holder; and then attaching the rollers to the inner surface of the holder, instead of to the outer. Also upper framing of the usual or modified form may be employed in conjunction with the mode of construction described. These and other variations—such as the number and form of the spiral guides or rails, the number and form of the rollers or sliding-blocks, and also of the radial angled rollers—may be made without departing from the peculiar character of the invention.

The claims for the invention are three in number—viz., “1. The construction of tanks or wells for gasholders, or the outer lift or lifts of such holders when telescopic, or both, with helical, spiral, or inclined rails, grooves, or recesses, built into or attached to the wall or face thereof, with the object of carrying the holder, or one or more lifts thereof as the case may be, by means of tangential rollers, sliding-pieces, or mechanical equivalents, attached to the lower ring or curb, or other convenient part of such holder, lift or lifts, for the purpose, and in manner substantially as shown and described. 2. The construction of gasholders, single or telescopic, with tangential or angled radial rollers, or both, or sliding-pieces or mechanical equivalents, attached to the bottom curb or ring of such holder or one or more lifts thereof, or both, as the case may be, with the object of causing the same to ride and rise and fall upon or within helical, spiral, or inclined rails, recesses, or grooves built into, forming part of, or attached to the wall of the tank or well or outer lift or both, for the purpose and in manner substantially as shown and described. 3. The construction and employment, for gas storing purposes, of holders and tanks or wells of the special character substantially as shown and described.”

THE USE OF SACCHARINE IN FRANCE.—A circular has been addressed by the French Director-General of Customs to the heads of all the Custom houses in the Empire requesting them to follow the movement of the importation of saccharine, either pure or in a mixed state, and to take note of the quantities which are henceforth introduced. He asks that they should inform him of these introductions, and forward as many particulars as possible as to the product, its value, &c. There was appended to the circular a copy of a letter sent last February by the Director-General of indirect taxes to the various agents, calling their attention to the subject of the introduction of saccharine into commerce, and requesting to be informed of any facts which would lead to the supposition that saccharine is used in place of ordinary sugar.

STILL ANOTHER USE FOR COKE.—There were shown in Manchester last week some interesting experiments with the portable “Sunlight” lamp, now being put on the market by the Gaseous and Liquid Fuel Supply Company, Limited, of Manchester. The apparatus (as described in *Industries*) consists of a steel boiler or retort, under which a moveable box containing the fuel is arranged. A wrought-iron chimney furnishes the necessary draught; and inside this chimney a thin tube ascends, which is fitted with a stop-valve and a small combustion chamber at the part protruding from the chimney. A pressure-gauge, a safety-valve arranged to blow off at a pressure of 40 lbs. per square inch, and an oil-inlet closed by a screw plug, are also provided. The whole of the apparatus is mounted on wheels, making it very portable. To work the lamp, the screw plug is removed and the retort filled with oil; and the plug is then screwed in tight, and the fuel under the retort ignited. The stop-valve remains closed until a pressure of about 5 lbs. per square inch is reached; then it is opened; and after allowing the air to escape, the gas is lighted, giving a brilliant flame, the intensity of which may be regulated by the stop-valve. The lamp shown gave a light of about 2500 candles while consuming 2 gallons of common blast-furnace oil per hour, and 1 to 1½ cwt. of coke in ten hours. The light was very brilliant and steady; illuminating the area of a circle of about 200 yards radius in such a manner that one could easily read at that distance. There was no smoke or smell perceptible, as the oil is converted into gas before being burnt. One man easily manipulated the lamp and wheeled it in any desired direction.

SOUTH-WEST OF ENGLAND DISTRICT ASSOCIATION OF GAS MANAGERS.

The Half-Yearly Meeting of this Association was held on Tuesday last, at Weston-super-Mare. After an inspection of the gas-works, under the guidance of the Manager (Mr. J. H. Gray), the business meeting was held at the Queen's Hotel—the President (Mr. H. Sainsbury, of Trowbridge) in the chair. Mr. Gray briefly welcomed the Association to Weston in behalf of his Directors, who, on account of the holiday season, and also some local meetings, were unavoidably absent.

The Hon. Secretary and Treasurer (Mr. Norton H. Humphrys, of Salisbury) read the notice convening the meeting; and the minutes of the last meeting were taken as read, on the motion of Mr. R. Ashton, seconded by Mr. H. G. Crowe.

The accounts for the year ending Aug. 31 last were adopted, on the motion of the President, seconded by Mr. James Lowe.

The President announced that the following list of applications for membership had been approved by the Committee; and he proposed its adoption:—Mr. S. Bark, Godalming; Mr. W. C. Bennett, Tiverton; Mr. C. V. Bennett, Wells; Mr. C. W. Folkard, Bournemouth; Mr. J. Griffin, Fareham; Mr. E. C. Riley, Great Western Railway Gas-Works, Swindon; Mr. H. F. Vincent, Frome. Mr. T. W. R. White, of Sherborne, seconded the proposition; and it was unanimously carried.

The election of officers for the ensuing year was then proceeded with. Mr. Ashton and Mr. Lowe volunteered to act as Scrutineers; and announced the result of the voting to be as follows:—

President:—Mr. J. H. Cornish, of Bridgwater.

Vice-President:—Mr. H. G. Crowe, of Wellington.

Members of Committee:—Mr. R. Beynon, of Torquay; and Mr. J. H. Lyon, of Cosham.

Auditor:—Mr. J. Nicholls, of Crewkerne.

Hon. Secretary and Treasurer:—Mr. N. H. Humphrys.

Mr. Cornish and Mr. Crowe having acknowledged the compliment offered to them in their election as President and Vice-President respectively, suggestions were invited as to the place of next meeting and Mr. Cornish proposed that it should be held at Bridgwater. Mr. White seconded the proposition; and it was unanimously carried.

The President, referring to the difficulty in obtaining papers for the meetings, said it had been proposed that the Committee should name subjects on which the members might prime themselves to speak. He invited suggestions from the members; also offers of papers for the next meeting. Mr. J. J. Jervis, of New Swindon, subsequently submitted the following subjects:—(1) To what extent are the advantages claimed for separate sections of hydraulic main realized? (2) The testimony of users of anti-dip valves. (3) Scoop-charging. (4) Scurfing retorts. He undertook to collect some information on the first question himself.

THE PRESIDENT'S ADDRESS.

The President, in the course of a few opening remarks, referred to the growth of membership in District Gas Managers' Associations generally; mentioning the newly-formed North of Ireland and the proposed Eastern Counties Associations, and wishing to all, both old and new, increased success and usefulness. He had pleasure in drawing attention to the fact that 10 new members had been elected in the South-West Association during the past year—a larger number than in any previous year—and that it now included 74 members, more than double as compared with the list produced at the first half-yearly meeting held at Sherborne ten years ago. Having alluded to the removal of Mr. W. W. Monk, who has gone to Australia, and Mr. Walter Thomas, now resident at Vancouver, British Columbia, he glanced at the recent discussions on the question of gasholder framing; resulting in Mr. Livesey's successful experiment at Rotherhithe, and the invention by Mr. Gadd, of Manchester. He concluded with a few remarks of a general nature.

MR. JERVIS'S PAPER.

Mr. J. J. Jervis, of New Swindon, offered some remarks on “Hydraulic Mains and Retort-Bench Bracing.” He said that he did not propose to direct attention to the size, shape, or material of the hydraulic main; but simply to its position. This was almost universally fixed upon as the top of the retort-bench—a good place for smoke, dirt, heat, and the general discomfort of the workmen who had to attend to anything in connection with it. The retort-bench formed a ready and inexpensive foundation for the hydraulic; but whether such was best for a reservoir that should be kept perfectly level and rigid, was open to question. Some engineers had contended that the thick tar found in the hydraulic was not due to the heat of the retorts. From “King's Treatise on Coal Gas,” he learnt that some had tried increasing the size of the hydraulic, or elevating it some distance above the retorts. Others had tried a continual stream of gas liquor, or occasional doses of hot water from the boiler, as a preventative of the formation of pitch. The drawing off of the tar from the bottom of the main instead of the top had also been practised; but yet the prevention of pitchy accumulation had not been completely attained. It was caused by the retention of the tar in the main, and by the passage of hot gas through this comparatively stationary tar, which evaporated the more volatile constituents. It was the hot gas, and not the radiated heat from the setting that did the mischief. By making the hydraulic so shallow as only to allow about 2 inches of tar below the bottom of the dip-pipe, it was stated that the tar kept perfectly fluid; there was no thick tar or crystals of ammonia; not a single stopped dip-pipe; and rarely a stopped

ascension pipe. Whilst not disputing that the choking of ascension and dip pipes might be due to the close proximity of the hydraulic to the retort-bench, and that therefore nothing would be gained by shifting it, he thought that the top of the retort-bench was not a desirable situation for the hydraulic. Again referring to "King's Treatise," he found it set forth that the standards supporting the hydraulic should have a substantial bearing on the piers separating the ovens. But he questioned whether a substantial bearing on the piers, which were part and parcel of the beds, and liable to movement with their expansion and contraction, was possible. The party walls needed renewal at times, and then there was anxiety and risk; strutting, slinging, and other means being resorted to, in order to maintain the hydraulic in safety. All this might be avoided by supporting it on girders or columns independent of the brickwork; and he had adopted this plan. At his works the hydraulic was supported on girders and columns absolutely free of the retort-bench; and the whole alteration for seven beds of five cost less than £40. This idea was not new. In fact, it was old, and had been condemned, on the ground of the prejudicial effect of the heat when drawing and charging, and the inconvenience of the projecting columns. But he found that the heat when drawing and charging was felt less on the platform which he had placed in front of the bench for the support of the hydraulic than in the orthodox position of the hydraulic; and the platform was far more convenient for the workmen than the hot brickwork on the top of the setting. It had been standing for six years; and although made of wood, and only 3 feet above the highest mouthpiece, it had never caught fire.

The arrangement of separate chimneys to each bed, and the fact that the beds were of different heights, interfered with the use of buckstaves and bracing in the usual manner; and he resolved to do without them. In "King's Treatise," again, it was stated that some considered tie-bars, &c., to be unnecessary, because they were liable to expand with the heat, and were sometimes burnt away altogether. But it was further stated that if they were fixed in proper position either above the brickwork, or if embedded well out of the reach of the heat from the flues, there was no danger of burning away; also, that they must be braced transversely as well as longitudinally, if they were to endure the wear and tear of many seasons, and prevent the piers from bulging, which would produce openings and crevices that would admit air and injure the draught. He might therefore ask if a long tie-bar did not allow a great deal of expansion? Also whether, apart from the hydraulic, the middle or inside beds were not supported by their neighbours one against the other; and therefore if it would not suffice to buttress the end beds only? And when a retort-setting was taken down, if the temporary strutting usually put up was intended only to support the hydraulic, or on account of expansion. Was not the matter of checking the expansion by means of tie-bars a question of degree only; for the heated brickwork must "go" somewhere, and he thought the only consideration was, "which way?" The point he had therefore to decide was whether, after relieving himself from care about the hydraulic, he need trouble about bracing the retort-bench? After four years work without bracing, he found that the inside walls remained plumb, and the end ones only went over about 2 inches in a height of 9 feet. The face ends of the piers had come forward about 3 inches, which would have been a bad job for the hydraulic if it had been supported on them. The expansion of the retorts was not more than formerly, but still he was convinced that some bracing was better than none at all, as it would curb the expansion to some extent, and so he determined to brace up again over all. As before mentioned, the formation of his bench did not admit of the usual kind of bracing; and he also wished to avoid the necessity for strutting when re-setting. He hit upon a plan by which each bed was held together independently of its neighbours. Each pier projected 2 inches at front and back, to allow of the fixing of angle-irons which were held together by diagonal tie-bars across the top. The cost of this arrangement was less than £45 for the seven beds.

The President having opened the discussion with a few remarks, Mr. Walter Fiddes, of Bristol, said that he had tried some settings of through retorts without bracing, but cracks appeared; and he found it advisable to put up buckstaves and tie-bars. He had also experienced considerable advantage from having large lumps of fire-clay of special pattern made for placing on the piers before the arches were turned, to take the springing of the arch. Cast-iron buckstaves would snap suddenly; whereas wrought-iron ones buckled and gave way gradually. He found that the expansion of the bracing when taking up a setting was about 3 inches, and the arch would rise or lift to the extent of 2 inches; so that it was necessary to gradually let out the screws when lighting up, and the reverse when letting down. After trying various devices, he preferred this plan, also adopting arrangements to let the heat down as gradually as possible—such as stopping all access of air, &c. By this means, he was able to get the retorts to last 1200 or 1400 days, counting working time only. He had used separate short chimneys to each bed for 40 years; and strongly recommended them as securing better heats with less fuel. Mr. J. Lowe, of Weymouth, said that, having been troubled with the breaking of cast-iron buckstaves, he had used wrought-iron ones made of two second-hand railway metals clamped together. These could be bought at 80s. per ton or so; and a 10-foot buckstave would only cost about 21s. They answered admirably. Where 14-inch party walls were used, and the bottom retorts were set close to the outside, it was necessary to keep the ascension-pipes out a few inches from the setting

sufficient to just clear the buckstave. Mr. S. W. Durkin, of Southampton, had long felt the need for supporting the hydraulic independently of the setting, especially in the case of long benches; and it was necessary to re-level at each time of lighting up. Some years ago he was much troubled with thick tar; but by adopting a simple plan for taking the tar off from the bottom of the hydraulic, he had quite cured that. He also connected a pipe from the liquor pump with the hydraulic; and was thus able to wash out the whole, overflows and all, with liquor every day. He remembered when iron retorts were used; and they did not strain the benches so much as the clay through retorts, which were brought more immediately in contact with the arches. In some double benches of iron retorts, the tie-bars were built in the brickwork; and when taken out it was found they had entirely rotted away. After trying various kinds of cast-iron buckstaves, all of which gave trouble by sudden breakage, he adopted wrought-iron ones; and these lasted well. He had some that had been in use for 20 years. He quite agreed with Mr. Jervis that the brickwork would "go" somewhere; and he condemned the plan of burying tie-bars in brickwork. They should always be in sight and clear of everything. The President, in closing the discussion, said that he had for some time taken his tar from the bottom of the hydraulic; and perhaps that was why there was little trouble with pitch at his works. Where tie-bars passed through brickwork, he had tried to protect them by surrounding them with drain-pipes; but still they would occasionally break at the point of fiercest heat.

NEWS FROM AN OLD MEMBER.

At this stage of the proceedings, the Honorary Secretary read a letter from a former member, Mr. Walter Thomas, now of Vancouver, British Columbia, in which he described his experiences in establishing a gas-works in the town. He had been compelled to erect the greater part of the works with his own hands, not having skilled labour; but they were now in working order, and successfully competing with electricity.

MR. DAVIS'S PAPER.

Mr. W. Davis, of Poole, next read a paper, entitled "A Remedy for Naphthalene." In the course of it, he remarked that some years ago he had to work a set of four purifiers, each 10 ft. square, which were so fixed that the inlet-pipes from a hydraulic centre-valve had to fall into the vessels. Consequently, whenever these were emptied, there was an accumulation of tarry matter to be cleaned out. Matters were further aggravated by the fact that the scrubber was small (only 18 feet high by 6 feet in diameter), and only about 25 feet away from the centre-valve; so it was only to be expected that a large quantity of condensable matter should be carried forward, and deposited at the bottom of the purifiers. As an improvement on this state of things, some 16-inch pipes that happened to be in stock were utilized to form a sort of condenser, being packed from bottom to top with 9 inch by $\frac{1}{2}$ inch boards, cut to the length of the diameter of the pipe, and placed crossways. A large rubbing surface for the gas was thus afforded; and this appliance was fixed between the scrubber and the centre-valve. It was found to be effective in removing condensable matter, and also proved to be useful in another and unanticipated way. Great trouble had previously been experienced with naphthalene; the connecting pipes of the station meter being frequently choked, and the inlet and the outlet pipes of the holders were also a constant source of trouble from the same cause. After the fixing of these pipes—which he termed "depositors"—the trouble from naphthalene entirely ceased. On studying the subject of the formation of naphthalene in gas-pipes, he concluded it must be formed by synthesis; the presence of moisture being a factor in its production.

During the discussion, the President remarked that he was not so much troubled with naphthalene as formerly. When a part of the condenser was out of use, he had known the meter-connections to be choked in a month. But, by attending to gradual condensation, although using the same kind of coal and under the same circumstances of working, he had prevented it, and had not experienced any stoppage on his works for quite 20 years. Mr. J. H. Cornish, of Bridgwater, was much troubled with naphthalene some years ago. The holder-connections were both choked; and he admitted steam to clear them, which caused the pipes to leak inside the tank, and put him to a great expense. But after adopting a foul main, and more gradual condensation, he completely got rid of naphthalene. Mr. R. Beynon, of Torquay, said that he had not quite succeeded in getting rid of naphthalene; but intended to enlarge his foul main. During the winter of 1885, he experienced great trouble in the mains and services. He was then advised to cover his condenser, which was an annular one. The next winter he covered up the condenser with sacking. The result was that, where he formerly had a dozen complaints or so per day, he now had only one or two. He now found most trouble in the autumn—from August to November. This he ascribed to the greater ranges of temperature which obtain at this period of the year. Mr. Crowe, of Wellington, wished to ask Mr. Jervis if the alteration in his hydraulic had caused any trouble with naphthalene. A friend of his worked with the hydraulic placed down the middle of the retort-house between two rows of retort-benches; and he was much troubled in this manner, and blamed the position of his hydraulic for it. Mr. Jervis said that he did not know what naphthalene was. Mr. A. Thomas, of Cowes, observed that some years ago he was periodically annoyed by the complete stoppage of a particular length of main about half a mile from the works. He could cure it for the time by pouring hot water in, or with the force-pump.

He afterwards erected a foul main, and enlarged the condenser at the works, and this completely cured it. Mr. Durkin remarked that he found trouble from naphthalene in the autumn, or whenever there was hot sunshine in the day and cold nights. Last winter a 16-inch pipe on the works was choked. It was deep in the ground; and he thought a tidal influence kept its surroundings damp and cold. He had great belief in the foul main, and doubted whether the one he had was large enough. Mr. Fiddes cited a case of two mains near the Houses of Parliament in London, which ran parallel, one of which gave great trouble from naphthalene, while the other was always clear. In the past he had had great difficulty with it; but since six larger mains had been used—24-inch in place of 9-inch or 10-inch—this was greatly obviated. He remembered that at one works it was a regular practice to clean out the holder-connections every Sunday. In one case the pipes remained clear for six years; and then stopped quite suddenly. He used vapour of naphtha, conveyed to the bottom of the pipes by a 1½-inch wrought-iron pipe carried down inside, to dissolve the deposit; and by this means, the pipes could be cleared in two hours. He had observed that when the temperature of the water in the holder tanks fell below 56°, there was a deposit of naphthalene formed. If they escaped at the works, they had it in the mains and services. When the main was exposed to moisture in low ground, the deposit was liable to accumulate; and he had also observed that the streets lamps would dwindle from this cause in regular lines—sometimes in a north-easterly direction, sometimes in another. This led him to think that magnetic influences might have something to do with the formation. Mr. Davis, in reply, thought that his argument as to the effect of moisture in the formation of naphthalene had been well supported in the discussion.

GASHOLDERS WITH SPIRAL GUIDES.

Mr. W. Gadd, of Manchester, then explained his system of constructing gasholders without the usual guide-framing; illustrating his remarks by two models, representing a single-lift and a three-lift holder respectively. He stated that he proposed to support the holder entirely from the bottom curb. The rollers were placed tangentially by preference, but could be radial if desired; and the guides, instead of being vertical, were disposed at an angle of from 45° to 60°—forming, in fact, a deep thread of a screw. Each roller was a point of support, so that the holder was held in just as many places round the ring as there were rollers. Each point of support formed a solid bearing, rendering the whole as stable as if resting on the floor. The entire structure—holder and tank—might be pushed over as if in one piece. The holder formed a cantilever of the elbow kind; the height being the extent of one limb, and the diameter that of the other. Therefore, if the wind pressure was concentrated near the top, the resisting leverage would still be much longer than the acting leverage. In this respect it was just the contrary to holders supported in the usual way; for the shallower he made the holder, the stronger it was. He then illustrated the power of his frame to resist unequal loading (such as an accumulation of snow on one side of the holder) by means of weights, and pointed out that under any circumstances, the strain on the guides was perfectly vertical. There could be no tilting, because the guides pointed in opposite directions on opposite sides of the tank; and therefore the rollers were gripped, as between the blades of a pair of shears. The principle of his invention was not affected by the manner in which the rollers and guides were designed—for instance, the rollers might be fixed on the tank and the guides on the holder, if preferred.

A conversational discussion took place on the action of the models, and the applicability of the invention generally, at the close of which the President thanked Mr. Gadd for his kindness in attending the meeting, and expressed the opinion that the models before them were a type of what the gasholder of the future would be.

MR. THOMAS'S PAPER.

Mr. A. Thomas, of West Cowes, read a paper describing "A Pressure-Gauge having no Fixed Joints." He commenced by referring to the importance of pressure-gauges on gas-works, and proceeded to notice the defects inherent to those generally in use—such as liability of the glass tubes to breakage, difficulty of cleaning, and high cost. In order to get rid of these objections, he had made many experiments, which had resulted in the production of the apparatus specimens of which were before the meeting. They consisted simply of two glass tubes one inside the other, with metal mountings, a specially-designed scale, graduated either upwards or downwards, and having no fixed joints.

Mr. J. J. Jervis, said he had very much pleasure in testifying to the efficiency of Mr. Thomas's gauge, having used one similar to it for six years, which he exhibited to the meeting. Mr. Lowe also showed a similar gauge, consisting of a glass tube graduated, and immersed in a narrow glass cylinder, which he said he had used in connection with the exhaustor for five years, to indicate either vacuum or exhaustor. He liked the principle very much; and strongly recommended it. Mr. Durkin also made a few remarks. The President observed that Mr. Thomas had certainly shown them a gauge that was a great improvement on the usual form of the apparatus.

CONCLUDING BUSINESS.

Mr. Lowe proposed a vote of thanks to the gentlemen who had come before them with papers and descriptions of apparatus that day, and thus contributed to make it a very successful meeting; and he specially referred to Mr. Gadd, who had travelled from Manchester at a day's notice. Mr. White seconded the proposition,

and it was carried by acclamation. Mr. Gadd having appropriately responded, the services of the President during the past year were acknowledged by a hearty vote of thanks, on the proposition of Mr. T. Hardick, of Salisbury, seconded by Mr. Crowe. In reply, the President proposed a vote of thanks to the Honorary Secretary and Treasurer, which was seconded by Mr. Durkin, supported by Mr. White, and carried unanimously. Mr. Humphrys acknowledged the vote; and the business portion of the meeting terminated.

The members and visitors subsequently dined together, under the chairmanship of the President. An excellent dinner was served in a room elegantly decorated for the occasion; and after the removal of the cloth, the usual toasts were given and responded to.

THE BRITISH ASSOCIATION AND STANDARDS OF LIGHT.

It may be remembered that a Committee appointed by the British Association for the Advancement of Science have for some time had under consideration the subject of standards of light. A report was presented to the Association at their meeting in Manchester last year, when the Committee stated that they had been anxious to carry out experiments on the various standards in use, but had been unable to complete their investigations owing to want of funds. The General Committee thereupon granted a sum of £100 for the purpose; and the matter stood over for further inquiry. The report of the Committee containing the results of the experiments they have since conducted was read by Professor George Forbes at the meeting of the Association at Bath on Monday last week. The full text of the document has not yet been published; but we are in a position to lay before our readers some of the results recorded therein.

The Committee confirm the conclusions arrived at by Mr. W. J. Dibdin in the report presented by him to the Metropolitan Board of Works.* They have included the following sources of light in their numerous experiments:—Ordinary candles, made by Messrs. Miller and also by Messrs. Brecknell and Turner; spermaceti candles of large diameter, six to the pound made by Messrs. Miller; the pentane standard; the pentane lamp; and the amyl-acetate lamp. The results of 118 experiments with each of these supply matter for the first appendix to the report.

With regard to the use of candles as a standard, it is stated by the Committee that the objections are numerous; but, as they are well known, only some of the more glaring are mentioned—such, for instance, as the fact that both the spermaceti and the wick are of indefinite chemical composition, so that so-called "standard" candles, conforming to the definitions of the Act of Parliament, can be made which vary largely in light-giving power. The Committee note with emphasis that the illuminating power of a candle in a closed photometer, or in any small ill-ventilated room, is considerably less than in an ordinary room. They also point out that the illuminating power of the candle is subject to fluctuations from minute to minute, owing to the variation in length and form of the wick, and to the filling and emptying of the cup of the candle according to the movements of the surrounding air. There is a point in the manufacture of spermaceti which is here noted. Manufacturers endeavour to remove the liquid portions of the spermaceti (what is called "sperm oil"), and obtain the "dry" spermaceti as free from it as possible. The resulting product has a higher melting point; and therefore burns with less facility. The manufacturers have now so far succeeded in this direction that candles have to be made with larger wicks; the result being that they give less light for a given consumption than candles with smaller wicks. Thus the effect of the improvement in spermaceti has been that standard candles give less light than they gave ten years ago, and probably still less than they gave at earlier dates, when the average consumption of candles of six to the pound was 140 grains per hour.

Professor Violle's standard of molten platinum is, in the opinion of the Committee, not a practical standard of light, although they are quite prepared to agree to the adoption of the light emitted by a square centimetre of molten platinum as a unit, but not as a standard of light.

There appears to be no prospect of any reliable electric standard of light, inasmuch as with incandescent lamps variations in the light are caused by the blackening of the glass bulbs surrounding the carbon filament and by the wasting of the filament. Moreover, the amount of radiation from the carbon depends upon the extent of its surface as well as upon the treatment to which it has been subjected.

With regard to the amyl-acetate lamp, the Committee remark that it is very constant; but its red colour is a serious objection to its use. This conclusion has been arrived at as the result of a very large number of experiments.

Mr. Vernon Harcourt's pentane standard the Committee consider as reliable and convenient; fulfilling the conditions required in a standard of light, inasmuch as it has no wick, and consumes a material of definite chemical composition. The experiments show that no alteration of light occurred when the specific gravity of the pentano was 0.632 or 0.628, instead of the specified value 0.630. The Committee note that the pentano standard is not the only possible standard which could be made possessing the necessary qualifications, but it is the only one that has come under their notice; and therefore they urge most earnestly the importance of undertaking such action as is possible to ensure the immediate rejection by the Board of Trade of the parliamentary candle as a

* See JOURNAL, Vol. L., p. 290

standard of light, and the adoption of the pentane standard in all future work.

In Appendix I., the results of the photometric observations made with the various sources of light are given; whilst Appendix II. deals with the results of experiments made with incandescent platinum. The photometrical observations were made with Mr. Dibdin's four-way photometer. As a standard of light, the flame of an Argand burner consuming coal gas enriched by being passed over pentane was employed. It was kept at a height of 3 inches, and only light from the middle of the flame fell on the discs. Candles were burnt at the first arm; the pentane lamp at the second (alternate reading being taken); the third arm had the amyl-acetate lamp; and the fourth, the pentane standard. Readings with the last two were also made alternately by a second observer simultaneously with the readings from the first and second arms—the observers from time to time changing their posts. In 118 complete candle tests, 86 differed by 1 per cent. from the day's average; 57 differed by 2 per cent.; 19 by 5 per cent.; and variations of 9 and 10 per cent. were occasionally registered. With the amyl-acetate lamp a difference of 2 per cent was obtained four times out of 118. The pentane lamp differed twice by only 1 per cent. from the average; and the pentane standard only once. Incandescent platinum, tried in various ways, proved extremely troublesome, and was even then very unsatisfactory as a source of illumination for purposes of measurement.

No discussion followed the reading of the report, although it was invited; but a vote of thanks was unanimously accorded to its author.

GASEOUS FUEL.

As briefly intimated in last week's JOURNAL, among the papers read before the Mechanical Science Section of the British Association, at the recent meeting in Bath, was one by Mr. J. EMERSON DOWSON, M. Inst. C.E., on the value of gas as fuel.

The author stated that at the York meeting of the Association in 1881, he explained an apparatus for making cheap heating gas by passing steam and air through incandescent fuel. Since then the apparatus has been considerably improved; and the gas made in it has been much used, not only for driving engines but for heating in many industrial processes. The composition of the gas necessarily depends somewhat on the quality of the coal used, and on the condition of the fire; the average composition being much the same, whether the gas is made at the rate of 1000 cubic feet per hour in a small generator or at the rate of 15,000 cubic feet per hour in a large one. In 1881, it was necessary for gas-engines to use five volumes of this generator gas for one of ordinary lighting gas to develop the same power. But since then some important modifications have been made in the "Otto" engines; and it is now necessary to use only four volumes. In 1881, only one engine of 3½-horse power had been worked with the author's gas; but since then a large number of engines have been worked with it—one indicating over 80-horse power. For more than four years Messrs. Crossley, the English makers of the "Otto" engines, have used this gas exclusively at their works for an average power of 150-horse power; and after a careful trial extending over 35 weeks, they have found that the fuel consumption was only 1·3 lbs. per indicated horse power per hour.* At these large works there is no chimney except in the blacksmiths' shop. Returns sent by eleven users of "Otto" engines working regularly in different places with the author's gas, and averaging 35-horse power each, show an average fuel consumption of about 1·3 lbs. per indicated horse power per hour, which is less than half that required for the best steam-engines of equal power. The results of other tests were given; and seeing that all have been obtained under practical working conditions, the record is certainly satisfactory. Many letters have also been received testifying to the ease with which the gas plant can be managed.

The author considers himself justified in saying that gas-power is now fairly launched in competition with steam-power; and he thinks, with the late Professor Fleeming Jenkin, that eventually the former will to a great extent supersede the latter. The author also thinks it tolerably sure that even better results than those already recorded will be obtained when an engine is really designed to give the best effect with generator gas. It is well known that in the "Otto" engines, each new charge of gas is diluted with a portion of the products of combustion from the previous charge; and this answers very well for ordinary lighting gas. But as generator gas (such as the author's) has only about one-fourth the explosive power of the other gas, it is a disadvantage to dilute it with products of combustion; and he feels confident that makers of engines will, sooner or later, find it expedient to design all engines of large power specially for cheap generator gas. The best fuel to use for making the gas is anthracite, as it does not yield tar or other condensable products, and does not cake in the generators. Ordinary gas coke can also be used with certain precautions.

Several instances were given of the use of this gas for heating of various kinds. At the Gloucester County Asylum it has been used daily for about five years. All the kitchen-work for the staff and inmates is done with it; and there is no ordinary fire in the kitchen. About 300 quarter loaves are baked with the gas every day, at a cost of about 1s. only for fuel. The gas is also used for two 12-horse power (nominal) "Otto" engines, which pump water and drive a dynamo for electric lighting. This gas is used on a

large scale at the cocoa-works of Messrs. Van Houten and Son, Messrs. Cadbury, and Messrs. Russ-Suchard and Co. Messrs. Onderwater and Co., of Dordrecht, use it for heating the drying-chambers in their starch-works. Messrs. Guittet, of Herblay, have for some years used it for making varnish; and they not only effect a considerable economy, but they avoid all risk of fire, which is a great consideration in varnish-works. This gas is also used by the Société Nestlé for soldering their condensed-milk tins; and more recently it has been adopted by Messrs. Huntley, Bourne, and Stevens, of Reading, not only for soldering, but for heating a large number of ovens in which japanned and varnished goods are stored. Messrs. Hillman, Herbert, and Cooper use this gas at their Coventry works and in Germany, for brazing with blow-pipes the joints of bicycles and tricycles, as well as for enamelling. On the Continent several firms use this gas for singeing silk yarns and textile fabrics. It is also used by several linen manufacturers in the north of Ireland for tentering, which they formerly did with hot air. The cost of the gas somewhat depends on that of the fuel; but, speaking generally, the equivalent of 1000 cubic feet of ordinary lighting gas costs from 6d. to 1s.

In the course of the discussion on the paper, Sir F. Bramwell spoke of the quantities of coal, especially slack and refuse, which, on account of their cheapness, were consumed in engines; and he characterized this as a careless waste of a valuable inheritance. Any invention that stopped this waste of coal, and made it impossible for an ignorant and careless man to use more than a certain amount of fuel, was, he considered, a great source of good. Mr. Fletcher asked Mr. Dowson whether he had considered the possibility of saving the ammonia produced with the gas. Professor Shaw remarked that carbonic oxide was largely present in the generator gas; and that this was a most dangerous poison. He thought it reflected great credit on Mr. Dowson that no accidents had happened where his plant had been installed. Mr. Williams said he had read that in one town in the United States, where this generator gas had been used, more deaths were caused by it than by ordinary gas in the whole of the States. Mr. Dowson, in reply, said that the quantity of ammonia was so infinitesimally small when the gas was made from anthracite (which was the material generally used), that it would not pay to seek for it. There was no disguising the fact that there was danger attending the use of carbonic oxide; but there was also danger with electricity and gunpowder when improperly handled. The best thing to do was to recognize the danger, and to take due precautions. It was very satisfactory to find that in such an Institution as the Gloucester County Asylum the gas had been in use for five years without any trouble being experienced.

DEVELOPMENT OF THE RUSSIAN OIL TRADE.—In the course of an article recently contributed to the *Newcastle Chronicle* by Mr. Charles Marvin, on the subject of the expansion of Russia in the Black Sea, he referred as follows to the trade of the oil region:—"Four years ago there was not an oil-tank at Batoum. I have lately received from there large photographs of some of the 47 now in position, holding collectively 20 million gallons of oil. Fifteen tank steamers, constantly running, and some of them holding 1 million gallons of oil, are insufficient for the growing demands of the trade. Nor is this activity confined to Batoum. From Poti an export of manganese oil has sprung up rapidly approaching 100,000 tons a year. Soukhum Kalé, twice the scene of a desolating Turkish descent, seems destined to share this general prosperity. A project is afoot to connect it by a branch line with the Trans-Caucasian Railway, and provide the latter with three outlets instead of two." The article was written just after the opening of the Novorossisk Railway, which taps the Black Sea petroleum region, and provides Russia with a new outlet for oil and liquid fuel, auxiliary to the Caspian supply now finding its way to Europe *via* Batoum.

SIR F. BRAMWELL'S INAUGURAL ADDRESS.—Confirmatory of the opinion expressed in our own columns last week as to the character of the address with which Sir Frederick Bramwell "edified" the British Association at the recent Bath meeting, the *Builder* says: "It is natural that daily newspaper critics should felicitate Sir F. Bramwell on having, in the words of one journal, made the presidential address of the British Association 'intelligible to ordinary readers;' and if the British Association were an institution for the popularization of science, this praise would, no doubt, be much to the point. Sir F. Bramwell's address was certainly intelligible to anyone, and formed a somewhat dramatic and occasionally humorous summary of the bearing of engineering and constructive improvements on the conduct of everyday life and occupation; but to our thinking something higher than this is to be looked for in the opening address of the British Association for the 'Advancement of Science.' The annual meetings of the Association tend to become more and more a kind of mere scientific amusement in the eyes of many of those who attend them—a form of mild dissipation; and however much this may be practically and unavoidably so in regard to a proportion of the audience, it is not desirable that Presidents of the Association should assist this tendency by reducing the presidential address to a piece of popular gossip on some of the superficial aspects of science. The address in question was, no doubt, amusing to many of those who listened to it, but it was not calculated to maintain the status and dignity of the annual meetings of the Association; and we hope its character will not be taken as a precedent for future addresses."

* This figure, was wrongly given in our brief report last week as 13 lbs.; and the error has been pointed out by Mr. Dowson for correction.

A NEW PIPE EXTRACTOR.

The extraction of cast-iron gas and water mains from the lines in which they lie in the trenches, is always a tedious business; but it is greatly expedited and cheapened by the simple device shown in the accompanying illustration, which is the invention of Mr. James W. Helps, Engineer of the Croydon Gas Company. The implement comprises a hinged clip for the main (which must, of course, be kept in different sizes to suit the diameters of pipes to be dealt with), and a forged block with a hand-screw, shown in

position at D in fig. 2. The method of application is as follows: Having uncovered a few lengths of main, the whole or a part of one pipe must be removed by the usual method of cutting out, so as to make a break in the line. The free end of the main is then slung as shown at A (fig. 2), so that it can be sprung by the lever B, worked from the road level, sufficiently high to permit of the introduction of a stout block, as at C, underneath the end of the next pipe. The clip, with the screw drawn back, is then tightly clasped round the spigot end of the second pipe, near to the face of the socket to be disconnected, as shown in fig. 2. The free end of the main is then again raised by the lever (or by tackle if it is a very large pipe), and allowed to drop suddenly upon the block C. The effect of this jar, repeated once or twice if necessary, will be to loosen the joint and draw the socket away from the top side. The screw is then turned until it bears against the face of the socket, and the process of lifting and dropping the main is repeated. The effect of this will be to still further loosen the pipe, which will be prevented by the screw from regaining its original position; and will therefore be drawn out somewhat at the bottom. A repetition of the process of lifting and dropping the pipe, and tightening the screw by hand whenever there is room for it to advance, will infallibly force the end pipe off the spigot without injury to either piece. The lead will, of course, be easily recovered. In turning the screw, no force is necessary; the hand being quite sufficient, as its object is not to push off the socket, but only to take up the slack caused by the repeated jarrings. Pipes can be drawn in this way in one-third or one-fourth the time required for the ordinary process of cutting out, besides saving all breakages of tools, &c. The device is in constant use at Croydon and elsewhere, and will be found of great advantage wherever any length of main has to be drawn.

NEW GAS ANALYSIS APPARATUS.—At the recent meeting of the British Association at Bath, Dr. W. W. J. Nichol showed a gas analysis apparatus, consisting of two parallel tubes communicating by means of stopcocks at the top and bottom respectively. One of the tubes is the measuring, the other the absorbing vessel. The apparatus may be readily used, and is suited for an analysis where accuracy approaching that obtained with the Bunsen apparatus is desired.

THE MINERAL PRODUCTION OF THE UNITED STATES.—Advance proofs have been received by *The Times* from Mr. David T. Day, Chief of the Division of Mining Statistics and Technology, United States Geological Survey, containing a summary of the statistics of the mineral production of the United States in 1887. The digest summarizes results which will also appear, in a more extended form, together with detailed statistics and descriptive and technical matter, in the forthcoming volume entitled "Mineral Resources of the United States, 1887." The aggregate value of the production in 1887 is stated to have reached \$538,056,345. The weight and value of the metallic products are given; and then follow the non-metallic mineral products, which are treated in like manner. The following are three of the items which fall under the latter head, and the figures in regard to which may be of interest to our readers:—Coal of all descriptions, 123,965,255 short tons (increase over 1886, 16,283,046 tons), valued at the mines at \$173,530,996 (increase, \$26,418,241). Petroleum, 28,249,543 barrels of 42 gallons each, value \$16,949,726; the increase over 1886 being only 139,428 barrels, with a decrease in the average value of 1½ cents per barrel. The production of natural gas in the United States in 1887 was equivalent to 9,055,000 short tons of coal displaced. This, at an average value of \$1 50c. per ton, would make the value of the coal displaced by natural gas (which is the measure of the value of the gas) \$13,582,500. In 1886 the corresponding quantity was 6,353,000 tons, worth \$9,847,150.

ELECTRICAL MATTERS AT THE BRITISH ASSOCIATION MEETING.

In addition to the references to electric lighting matters made at the recent meeting of the British Association at Bath by the President (Sir F. Bramwell), in his Inaugural Address, and by the President of the Mechanical Science Section (Mr. W. H. Preece), in his address to that Section—both noticed in the *JOURNAL* last week—several other subjects in this department of science were brought forward, which may now be dealt with together.

THE ELECTRICAL TRANSMISSION OF POWER.

The first matter to claim attention is the discourse delivered by Professor W. E. Ayrton in the Drill Hall, on the evening of Friday, the 7th inst., on "The Electrical Transmission of Power." The gathering was fully as large, and almost as brilliant, as on the occasion of the delivery of the presidential address; and the elaboration of the subject by the lecturer gave rise to a most successful series of experiments, in which many striking and wonderful effects were produced by the electric machines and other apparatus exhibited on the platform and on the intervening space between it and the audience. The President of the Association (Sir F. Bramwell) occupied the chair; and, in introducing the lecturer, paid a graceful tribute to his services in the cause of scientific education and science generally.

Professor Ayrton began his address by asking "What is power, and why should we wish to transmit it?" Power, he said, had one very definite meaning in science, and several rather vague meanings in practice. By power, an engineer understood the rate of doing work. To factories, power was indispensable. The looms, the lathes, or whatever the machinery used in the factory might be, must either be worked by hand or by foot in the old style, or it must be connected with the steam, gas, or water engine in the new. In America there are 6000 electric motors working machinery; in Great Britain hardly 100. But it was not only in transmitting the power from the steam, gas, or water engine of a factory to the various machines working in it, that electricity could be utilized. An incredible amount of power was daily running to waste in this and other countries, because many of the rapid streams of water were too far away from towns for their power to have been hitherto utilized. Assuming, as a low estimate, that a large well-made steam-engine burnt only 2 lbs. of coal per horse power per hour, the coal consumption which would be equivalent to the waste of power at Niagara would exceed 150 million tons per annum, which at only 5s. or 6s. per ton meant some £40,000,000 sterling wasted. It was a well-established fact that large steam-engines could be worked more economically than small ones; and that therefore, if it were possible to economically transmit the power from a few very large steam-engines to a number of small workshops, there would be a great saving of power as well as of time.

There were four methods of transmitting power to a distance: (1) By a moving rope; (2) by air compressed or rarefied at one end of a pipe operating on an air-motor at the other end; (3) by water forced through a pipe working a water-motor; (4) by electricity. For short distances of about a mile there was no system of transmitting power in a straight line along the open country so cheap to erect, and so economical of power, as a rapidly-moving endless rope. But the other systems gave much greater facilities for distributing the power along the line of route, were much less noisy, and far surpassed wire-rope transmission in economy. Distribution of power by water pressure was the plan that had hitherto found most favour in this country. The economy of this system was so marked, and the success that had attended its use so great, that, did he not feel sure that electricity offered a grander system still, it would be with fear and trembling that he should approach his subject. Some six years ago *Punch* drew the Giant Steam and the Giant Coal looking aghast at the sucking babe Electricity in its cradle. That babe was a strong boy now. Let the Giant Water look to his laurels ere that boy became a man. For the electric transmission of power even now bade fair to surpass all other methods in economy in the consumption of fuel, more perfect control over each individual machine, ability to bring the tool to the work instead of the work to the tool, and greater cleanliness. There was one more advantage possessed by this method of transmitting power to which no other could lay claim. The power which during the daytime might be mainly used for driving machinery, could, in the easiest possible way, be used during the night for giving light. By turning a handle one way, the electric current coming by one wire and returning by another, worked the electric motor; by turning it the other way, the current which came and returned by the same wires as before, kept the electric lamp glowing. It might be said that the transmission of power by coal gas fulfilled this condition; but so also did the transmission by a loaded coal waggon. In both these cases, however, it was fuel itself that was transported, and not the power obtained by burning it at a distant place.

From this point, the lecturer proceeded to examine in detail the electric transmission of power. This power, he remarked, of producing an action at a distance of many yards, or it might be many miles, by aid of electricity, without the visible motion of any substance in the intervening space, was by no means new. But until about ten years ago, the facility that electricity gave for producing signals almost instantaneously at a great distance, was the main thing thought of. The electric power consumed for sending telegraph messages was so small, the amount of power lost *en route* comparatively so valueless, that the telegraph engineer had no need to trouble himself with those considerations that

govern us to-day when we are transmitting power large enough to work a factory or an electric tramway. In the last three of the systems on his list, some form of power—such as flowing water or the potential energy stored up in coal, wood, zinc, or other fuel—had initially to be utilized. This power was given to some form of air, water, or electric pump, which would transfer the power to the air, water, or electricity by which it was conveyed to the other end of the system. There it was re-converted into useful mechanical power by means of an air, water, or electric motor. The lecturer then described the improvements effected in motors. It had been shown, he said, that, since the power developed by the generator and motor depended on the product of the current into the electric pressure, while the loss when power is transmitted through a given wire depended on the square of the current, and was independent of the electric pressure, the economical transmission of power by electricity on a large scale depended on the use of a very large electric pressure and a small current, just as the economic transmission of such power by water depended on the use of a very large water pressure and a small flow of water.

Proceeding to speak of the methods by which electrical transformation may be effected, Professor Ayrton said that in America alternate-current transformers were, owing to the remarkable enterprise of Mr. Westinghouse, used to light 120,000 incandescent lamps in 68 towns. The efficiency of a well-made alternate-current transformer was very high; being no less than 96·2 per cent. when the transformer was doing its full work, and 89·5 per cent. when it was doing one-quarter of its full work. It certainly seemed most remarkable, and reflected the highest praise on the constructors of electrical machinery, that motor power could be converted into electrical power, electrical power at low pressure into electrical power at high pressure, or electrical power at high pressure into electrical power at low pressure, or, lastly, electrical power into motor power, in each case with an efficiency of 94 per cent. As a further illustration of the commercial importance of electric transformation, the lecturer showed some experiments on electric welding—one of the latest developments in electrical engineering. To weld a bar of iron 1 square inch in section requires a gigantic current of some 13,000 amperes. To convey this current even a few yards would be attended with great waste of power; consequently, while an enormous current is passed through the iron to be welded, only a comparatively small current is transmitted along the circuit from the dynamo to the welding apparatus. [Mr. Fish, the representative of Professor Elihu Thomson, of America, to whom this apparatus is due, then showed the welding together of two bars of square tool steel, the edge of each bar being $\frac{3}{4}$ inch; the operation being entirely completed in 15 seconds. For this experiment an alternate current of 20 amperes was produced by a dynamo placed at some distance from the building; and this current was converted, by the transformer on the platform, into one of 9000 amperes—large enough for 12,000 incandescent lamps, if they were placed parallel and the current divided among them. He then welded some thicker bars; and lastly two pieces of aluminium.]

After describing in detail the improvements made of late years in dynamos and motors, the lecturer called attention to the perfection to which the system of economical distribution with accumulators, originally proposed by Sir William Thomson in 1881, has been brought by Mr. King, the Engineer to the Electrical Power Storage Company. On this point he remarked that in less than twenty years from Gramme's practical realization of Pacinotti's invention, we have power transmitted over considerable distances by electricity, with only a total loss of 25 per cent.; whereas the combined loss in an air-pump and air-motor, or in a water-pump and water-motor, is 40 per cent., irrespective of the additional loss by friction or leakage occurring *en route*. We could not help feeling, he continued, that we were rapidly arriving at a new era; and that it would not merely be for the inauguration of the quick transmission of our bodies by steam, or the quick transmission of our thoughts by telegraph, but for the economical transmission of power by electricity, that the Victorian Age would be remembered. To burn coal to work dynamos, and to use the electric current to light our houses and our streets, was clean and economical; to use the current to warm our rooms was clean but wasteful, on account of the inefficiency of the steam-engine. But when the dynamos were turned by water power which would otherwise be wasted, the electric current might be economically used, not merely to give light, but also to give heat. And when the electric transmission of power became still more perfect than at present, even to burn coal at the pit's mouth, where it was worth 1s. a ton, might, in spite of the efficiency of the steam-engine being only one-tenth, be the most economical way of warming distant towns where coal would cost 20s. a ton. Let them think what this would mean. It would mean no smoke, no dust, a reform effected commercially which the laws of the land on smoke prevention were powerless to bring about—a reform effected without the intervention of the State, and therefore dear to the hearts of Englishmen.

But of all the many commercial uses to which the electric current might be put, probably, after the electric light, electric traction had, Professor Ayrton went on to remark, most public interest. While it cost 6d. or 7d. to run a car one mile with horses, it only cost 3d. or 4d. to propel it electrically. The lecturer proceeded to describe the "series" system of propelling electric railways, at work in America at Denver (Colorado); stating that a "series" electric tramway 12 miles long, on which 40 cars are to be run, is in course of construction in Columbus (Ohio). The first

track on which electric trams were run in series was the experimental "Telpher Line," erected in Glynde in 1883, under the superintendence of the late Professor Fleeming Jenkin, Professor Perry, and himself, for the automatic electric transport of goods. In addition to the small waste of power and consequent diminished cost of constructing the conductors that lead the current into and out of the passing trains, the system had another very marked advantage. Some years ago it was pointed out that when an electric train was running downhill, or when it was desired to stop the train, there was no necessity to apply a brake and waste the energy of the moving train in friction, because the electric motor could, by turning a handle, be converted into a dynamo, and the train could be slowed or stopped by its energy being given up to all the other trains running on the same railways, so that the trains going downhill helped the trains going uphill, and the stopping trains helped the moving trains. Economy was one feature that gave electric traction the right to claim attention; safety was another—human fallibility, in fact, was eliminated. It might be interesting to mention that the last difficulty in telpherage, which consisted in getting a proper adhesion between the driving-wheels of the locomotive and the wire rope, had now been overcome. After several years of experimenting we had in telpherage, he ventured to think, at last a perfectly trustworthy, and at the same time a most economical method of utilizing distant steam or water power to automatically transport our goods, and in time it might even be our people, over hills and valleys without roads or bridges, and without interfering with the crops or the cattle or the uses to which the land might be put over which the telpher trains pursued their snakelike way. We had, in fact, the luxury of ballooning without its dangers.

ELECTRIC LIGHTING IN AMERICA.

This was the subject of a paper read by Professor Forbes in the Mechanical Science Section on the 10th inst. He observed that on landing in England, people were particularly struck everywhere with the dimness of the lighting in our public thoroughfares. In America they could not go to a single town without seeing abundance of arc lighting in the streets. He did not speak simply of the influential towns, such as New York, Philadelphia, or Boston, but in many of the out-of-the-way places in most distant parts of the States. Where gas had never penetrated, there the electric light had fixed its position, and was being used frequently. The chief progress in central station work had been in three directions—(1) arc lighting; (2) incandescent lamps with the wire system; and (3) incandescent lamps with converters on the Gaulard-Gibbs system. The number of arc lights was now about 300,000. He particularly commended to notice the growth of incandescent electric lighting. He said it had been estimated that there were $2\frac{1}{2}$ million incandescent lamps used in the United States; and he believed the factories at that moment were capable of turning out 10,000 of such lamps every day. The annual increase in the number of incandescent lamps in the States must be counted by millions per annum. The growth of central station lighting was in great measure attributable to the efforts of Mr. Westinghouse. This gentleman had devoted himself very earnestly to the improvement of this system. Towns in America did not now order the separate apparatus for starting a central station, but were supplied with the whole station complete ten days after ordering. At the present moment about 300,000 lamps were being lighted by Mr. Westinghouse's alternating current plant. It had been said that in England they did not go ahead so much as people did in America; and he attributed much of the hindrance to English progress to the iniquitous Electric Lighting Act. Proceeding to comment on the American system, Mr. Forbes pointed out the small use made of accumulators in the States, where they were regarded as very unreliable in their action. Electricity of high potential was supplied by the stations; and by the introduction of an induction apparatus, it was converted into a harmless strength for consumers' use. Dealing with the various forms of electric machinery and its adjustment, Mr. Forbes urged the advantage of several medium-sized dynamos, rather than putting the whole work on to one large machine, which would be uneconomical when working at less than its maximum power. He advocated the use of 50-volt lamps rather than those of 100 volts, as being the result of American experience. American engineers had, he said, arranged to produce 1000 volts, instead of 2000, which was the custom in England.

ELECTRICAL DISTRIBUTION AND MEASUREMENT.

These subjects were dealt with in papers read before the same Section by Mr. H. Edmunds and Mr. W. Bayley Marshall—the latter for the author, Mr. W. Lowrie.

Mr. Edmunds first glanced at the questions of direct supply, and then at secondary generators. He showed that both these systems were dependent upon the regular work of the machinery at the central station. To remove this difficulty, his system of using secondary batteries had been brought into use. Groups of cells were placed in various portions of the district to be lighted; each group being divided into a given number of sections. If the group was divided into four sections, it was arranged that three should be sufficient to supply the local demand, while the fourth was being charged from the central station. The newly-charged section was switched on to the local supply, and another section charged; and thus a constant supply was maintained. The action was automatic—the strength not being allowed to fall below a certain point. The author claimed that the system was advantageous, owing to the even pressure of the current supplied to the lamps, the moderate

size of the conductors, the safety, and the absence of risk of failure of supply.

Mr. Lowrie, in his paper on "The Measurement of Electricity in a House-to-House Supply," described a method designed by him and his colleagues for the purpose of measuring alternate currents as used for house-to-house distribution with the converter system. He said it was well known that with such a system it was possible to get a current first in one direction and then in the opposite direction, and any chemical effect of the one current was destroyed in the reverse action. Messrs. Lowrie, Hall, and Kolle proposed to insert in the main an accumulator, having an electro-motive force of 2 volts. This force during one half-alternation aided the ordinary current; during the other half it opposed it. Thus if the original electro-motive force was 100 volts, this became when aided 102 volts; when opposed, 98 volts. If a depositing cell were placed in circuit, deposition would at one time take place due to the electro-motive force of 102 volts, and during the reverse action of only 98 volts; leaving the action of 4 volts over one-half the time—that is, of 2 volts over the whole time—and this gave the means of exact measurement required.

In proposing a vote of thanks to the readers of the papers, the President (Mr. W. H. Preece) said he desired to protest against the idea that the inaction in regard to electric lighting in this country was solely due to the Electric Lighting Act of 1882. This Act was in no sense or shape an interference with the action of corporations. Some fifty or sixty corporations obtained Provisional Orders under the Act, but never carried out the powers conferred by their Orders. The fact was that electric lighting had not even yet become sufficiently advanced for corporations to be justified in investing the money of the ratepayers in it. It was impossible not to be impressed with the wonderful activity of the Americans; but he considered that in this country it was best to work slowly and with certainty, as was being done at the present time. In a year or two they would be able to learn all that was necessary in England; and they would then go ahead, and establish a system infinitely better than anything now existing.

THE SCHÜLKE GAS-LAMP.

Among the many regenerative lamps to which attention has been lately drawn, one that appears worthy of special notice is the Schülke lamp. The good principles underlying the construction of the lamp have more than once been pointed out by us; but it has been principally in connection with lamps of the larger types. Too little attention has hitherto been paid to the perfecting of small regenerative lamps, to replace the ordinary flat-flame burners of everyday life; and serious objections have been found to nearly all those which have aimed at this end. The Schülke system has been adopted in this latest form of the lamp; but the details have been considerably modified and improved by the Woodhouse and Rawson Manufacturing Company, who have been at work many months on the small type of lamp, with a view to producing an efficient, durable, and cheap lamp of small consumption. The regenerative portion of the lamp consisting of pure nickel, porcelain, fire-clay, and asbestos would appear to promise it a long life; while the burners which are the ordinary flat-flame steatite type are shown by experience to be more lasting, and to give less trouble, than any form of perforated ring-burner. The air spaces are all full and large, so that choking is impossible; while the size of the lamp is probably less than that of any other lamp of equal consumption. Owing to the form of burner employed, the flames are of remarkable steadiness, and in draughty passages, and similar positions, scarcely a flicker can be seen. The 4-foot type of lamp has been carefully tested by one of our leading authorities; and it has given a duty of between $5\frac{1}{2}$ and 6 candles per cubic foot of gas consumed—without reflectors of any kind, and burning gas of the quality usually supplied in London. This result is remarkably high, and will probably lead to the adoption of a still smaller type where less illumination is required.

The Schülke Gas-Lamp Company, whose offices are at No. 11, Queen Victoria Street, E.C., are now turning their attention to the question of lamps for street lighting; having, we learn, worked out a simple and easy plan of lighting the lamp by the ordinary method, and so overcoming one of the principal stumbling blocks to the employment of the regenerative system for the lighting of public thoroughfares.

THE REPLENISHMENT OF UNDERGROUND WATER SUPPLIES.—This was the subject of an instructive paper read at the recent meeting of the British Association at Bath by Mr. Bailey Denton, C.E., F.G.S. The author drew attention to the capabilities existing of replenishing the subterranean supplies of the water-bearing strata by shafts sunk down to the line of their saturation; taking the Thames and its basin to illustrate his views. He referred to an opinion given in his evidence before the Royal Commission on Water Supply in 1867, that if towns on the banks of rivers were to lift their sewage and foul liquids on to absorbent lands lying 100 to 150 feet above them, they would not only free the rivers from pollution, but help to maintain their overflow with certainty. Winchester, Basingstoke, and other towns situated on the chalk, had adopted this mode of sewage disposal without injurious effect; and the author submitted that while such instances testified to the purifying powers of aerated chalk, they afforded proof that when superfluous waters were let down into the water-bearing strata from above, they would *pro tanto* spread, and naturally raise the line of saturation and the outflow of springs.

RESERVOIR GALLERIES AND CONDUITS IN NAPLES.

In a recent number of the *Engineering and Building Record* of New York, an article appeared on the above subject, translated from a paper by M. Flamant, in the *Annales des Ponts et Chaussées*. The particulars given below are taken therefrom.

Among the works executed in 1882-4 for the distribution of the Naples water supply, the special features of the reservoirs are sufficiently interesting to be here described. Instead of building them at great cost of solid masonry, advantage has been taken of the sand-rock formation to excavate in the heart of the mountain vast galleries which serve for reservoirs. In this way complete solidity was assured and simplicity of construction, as well as the great advantage of protecting the enormous quantities of water from the influences of exterior temperature, since the receptacles were constructed at a great depth below the surface of the ground.

The most important of these reservoirs—that for low and mean services is dug in the hill of Capodimonte, and is composed of five grand parallel galleries at a mean depth of 164 feet. They are 35·4 feet high by 30·33 feet wide, separated by a solid wall of rock 30·33 feet in thickness. The three first galleries are each 836 feet long; and the united length of the other two is 1217·4 feet—making a total of 3725 feet wide.

The depth of the water being 26·25 feet, gives a total capacity of 21,187,000 gallons. The surface of the galleries up to 1·64 feet above the water is covered with Grenoble cement from $\frac{1}{2}$ inch thick above to 2 inches below, applied in two coats, of which the second is composed of equal parts of sand and cement. Aération is secured by seven air-shafts. The working apparatus is placed in three service galleries, separated by partitions of natural rock, superimposed above each other, and having a direction perpendicular to that of the reservoir galleries. The high-service reservoir is similar, but has a capacity of only 5,295,000 gallons.

These reservoirs are supplied by the Cancellò syphon, which discharges 26,500,000 gallons of water daily. It is composed of three conduits, one of 2·3 feet internal diameter for the upper reservoir, and two others, each 2·62 feet, for the lowest mean services. The length of the first is 14 miles; and it discharges 60·3 gallons per second. Each of the other two is 11·6 miles; and they together discharge 245 gallons per second.

These conduits are exceptional from the great pressures they sustain at their lowest points where the heads are 610 feet and 361 feet for the small and large ones respectively. The thickness

was calculated by the usual formula $e = \frac{H D}{2 R}$ where e is the thick-

ness in millimetres and H the head and D the diameter—both in metres; R being the maximum strain per square millimetre, taken at 2485 lbs. per square inch. For the 27 $\frac{1}{2}$ -inch conduit, a thickness of $\frac{3}{4}$ inch was used for all heads up to 295 feet, gradually increasing for greater heads until a thickness of 1·46 inches was reached for the maximum head of 613 feet. Similarly, for the 31 $\frac{1}{2}$ -inch conduit the thickness was 0·8 inches for all heads up to 295 feet, with a maximum thickness of 1·02 inches for a head of 377 feet.

The pipes were furnished by the Terni shops, and, except where it exceeded 25 atmospheres, were proved at the shops to a pressure of double the working strain; and after being set, each section was again tested to a pressure five atmospheres greater than the computed head for that place. The conduits were put in operation by means of an 8-inch pipe parallel to the 27 $\frac{1}{2}$ -inch conduit, and connecting its highest and lowest points. Each conduit can be operated independently of the others. The water is introduced from below; and the air escapes through vents at all the summits, and at distances not exceeding 1640 feet apart in the horizontal portions. The sections of the pipes weighed upwards of two tons each; but the difficult operation of laying them was successfully accomplished, and they have been working without any accident since 1885.

THE PROPOSED GAS MANAGERS' ASSOCIATION FOR THE EASTERN COUNTIES.—We learn from Mr. H. Wimbhurst, of Sleaford (who is acting as Honorary Secretary *pro tem.*), that the preliminary meeting of gentlemen interested in the scheme for founding a Gas Managers' Association for the Eastern Counties will be held at Peterborough to-morrow week (the 26th inst.) at 1 o'clock.

WATER SUPPLY PROJECTS FOR JAPAN.—The Belgian Chargé d'Affaires at Yokohama has announced a project for the distribution of water in a number of Japanese towns. The town of Yokohama was last year benefited by a system of water supply, the plans and carrying out of which were placed in charge of General Palmer, an English engineer, engaged specially for this purpose by the Governor. The enterprise was apparently successful; and, encouraged by the example set before them, the municipal authorities of several other large towns have been studying the means of executing similar works. In fact, at Kobe, Osaka, and Hakodate, the preparatory plans and estimates have, it is stated, already been arranged. At Tokio also, the capital of the Empire, a similar project is under consideration; but it is uncertain whether the Government itself will undertake the carrying out of a system of water supply, or entrust the work to a company. The principal difficulty at present seems to be the means of raising the necessary funds; and it is estimated that a sum of 6 million yens (or about £1,000,000) will be required. Tokio actually has a population of 1,000,000 people; and, according to the present project, the water supply would have to be based on a population of 2,000,000.

Register of Patents.

GAS-LAMPS.—PUGH, R. W., of Pendleton, near Manchester. No. 13,862; Oct. 13, 1887. [11d.]

This invention is applicable more particularly to pillar and bracket lamps; the object of the invention being to adapt such lamps to burning gas on the "regenerative" principle. It is also applicable to suspended lamps and lamps for outside use.

Fig. 1 represents a vertical section of a pillar or street lamp with a polygonal glass body, air-tight excepting at the top and bottom. To supply air to the top of the flame above the burner B, a number of tubes C are employed, opening outwards, and radiating towards a vertical central tube D (of larger diameter), which passes downwards to a small distance above the top of the burner. Over the entrance to the mouth or outward ends of these radiating tubes is fitted a shield or baffle-plate E, to protect the inlets from any sudden rush of wind. Under the burner or burners a central tube F is fitted, similar to the one above, and terminating just below the burner. This is to supply air beneath the flame. Below this tube (the lower end of which is open) a shield is formed at the bottom of the lamp, so as to protect the entrance to the tube—which is the air-inlet—against rough winds or sudden rushes of air. This shield is made of metal rings or plates, some of which are fastened to a disc above, and alternate ones to the bottom of the lamp. The edges of these discs pass each other, but allow a sufficient space for the passage of the air into the mouth of the tube F beneath the burner or burners. The gas-supply pipe K in this case passes upwards through the bottom of the lamp to the burner; or it may pass downwards from above, as in some of the other forms of lamp. In the former case the supply-pipe is carried up above the burner, the upper part being of a smaller diameter; and this part is enclosed in an outer pipe L, so arranged that the gas is compelled to pass up to the top of the inner pipe, and down the hollow space between the two pipes, before it can arrive at the burner B. In this way the gas becomes heated before it mixes with the warm air supplied by the tubes D and F; and the brilliancy of the light is increased.

In a modification of the above (represented in fig. 2) suitable for suspension from the ceiling of an apartment or building, for the purpose of diminishing the shadow on the ceiling, the reflector which is usually employed inside the glass around the upper margin, is dispensed with; and the glass is made more globular than hitherto. This reduces the diameter of the top of the lamp, and consequently the shadow on the ceiling; and to complete the effect, the tube or warm-air cell D, which is above the burner B, is brought to a greater depth than usual in the globe—thereby causing the rays of light to spread more freely.

GAS-LAMPS.—PUGH, R. W., of Pendleton, near Manchester. No. 13,940; October 14, 1887. [8d.]

This invention, relating principally to outside pillar and bracket lamps, consists of a method of constructing such lamps so as to adapt them to the regenerative principle.

The illustration represents a vertical section of an outside bracket suspended lamp with polygonal outer glass or body, and radiating tubes B corresponding with the angles of the glass body, and open at both ends. The outer ends of these tubes are open to the atmosphere, while

the inner ends are connected to a larger central tube C, which passes downwards and terminates just above the top of the burner D, so as to supply air to the upper side of the flame. Other radiating tubes E are carried downwards from the same point along the angles of the glass body, and communicate with another similar central tube F, which is carried upwards from the bottom of the lamp to supply air to the lower side of the flame. Over the entrances to the mouths of these radiating tubes, a shield G is formed, so as to protect the inlets from currents of air. Above the upper central tube, is a chimney H, to allow the products of combustion to escape. In this form of lamp, the heat from the flame acts upon the upper central tube; and thus warms both the air and the gas in the supply-pipe I before they arrive at the burner.

In some cases in suspended lamps, where the gas-supply pipe is brought down from above, there is placed at the lower end of the gas-pipe an enlargement forming a cell or regenerator for heating the gas, and also serving to spread the flame and reflect the light. In this modification the upper central tube C and radiating tubes B and E are dispensed with. All the air enters at the bottom, and is there divided. A portion passes up an inner tube, and through the centre of the circular burner to the upper part of the flame; while the other portion passes upwards between the tubes, and supplies the lower side of the flame. The burner is provided with a hollow wall; and the gas passes into it through cross tubes.

The patentee also describes the application of this principle to a pillar lamp, wherein the gas-supply pipe is carried up from beneath. In this case the air also enters from below; one portion passing upwards through the centre of the burner around the gas-pipe. The upper part of this gas-pipe is enclosed within a second pipe, the top of which is enlarged so as to form a cell or regenerator for heating the gas. It also serves to spread the top of the flame. A slight distance above the cell is placed a cap; leaving a space between for the circulation of air, so as to keep the gas from becoming over-heated. This cap also forms a reflector for the light. The burner is further fitted with a cross-pipe, through which the gas passes from the outer gas-pipe after it has gone through the regenerator; so that the gas becomes further heated before it issues from the burner, and mixes more freely with the heated air.

GAS-ENGINES.—BARKER, T. B., of Birmingham. No. 14,027; Oct. 15, 1887. [8d.]

This invention consists primarily of certain improvements on patent No. 1388 of 1881, which described mechanism for igniting the mixture of gas and air in the cylinder of the engine, consisting essentially of a rotating disc having a series of equidistant radial slots. The rotary motion of the disc is intermittent, and is produced by a pawl acting on a ratchet formed on the periphery of the disc; and the ignition of the charge is effected when, by the motion of the disc, one of the radial slots in the disc is brought between a stationary ignited gas-jet and a passage opening in the charged cylinder.

The first part of the present invention has reference to this igniting mechanism; and it has for its principal object to prevent the noise attending the working of the mechanism as originally constructed. Accordingly the radiating slots in the rotating disc are made of much larger capacity than in the original invention; the slots constituting small gas chambers. Instead of the slots simply opening a communication between the igniting gas-flame and the charged cylinder of the engine, each slot as it approaches the igniter flame is caused to receive a charge of gas; and in passing the flame the charge becomes ignited. By the motion of the disc, the charged slot (the gas in which has been ignited) is rapidly brought to the opening in the charged cylinder of the engine, the detonating mixture in which is ignited by the flame carried by the slot. By this arrangement, the ignition of the mixture in the cylinder is effected, practically speaking, noiselessly. The igniting flame is situated in a small chamber formed in a fixed plate or disc, against which the rotating slotted disc works approximately gas-tight.

The second part of the invention has for its object to bring to rest the rotating slotted disc when, by the action of the governor, the cylinder of the engine is not being charged with gas. For this purpose, a lever is so connected with the governor that, as the balls of the governor rise, the long arm of the lever rises; and as they fall the arm descends. The short arm of the lever is connected with an incline, to which it communicates a sliding motion. As the balls of the governor ascend and cut off the supply of gas to the cylinder of the engine, the incline is made to advance under the end of the pawl, which actuates the rotating slotted disc, and raises the pawl out of range of the ratchet teeth on the periphery of the disc. The disc is consequently not actuated by the pawl; and the wear and tear of the disc is arrested and the waste of the igniting charges of gas prevented. When by the diminished speed of the engine, the governor balls descend and restore the supply of gas to the cylinder, the incline by which the pawl was supported out of action is at the same time withdrawn; and the pawl again coming into action, the igniting mechanism is operated. The supply of gas to the cylinder and the working of the igniting mechanism thus take place simultaneously.

JOINTINGS OF PIPES.—FEATHER, T., of Mirfield. No. 9278; June 26, 1888. [6d.]

The illustration shows longitudinal sections of portions of the two outer ends of a pipe constructed according to this invention.

These outer ends form a socket as well as a spigot for each other; and they are of somewhat a bevelled shape, in order to form a kind of

seating for the corresponding parts. On the pipe B are formed two three, four, or more lugs or ears D to which are attached the hooks E, made so that they will easily engage with the projecting parts F. In order to enable the parts to thus engage with each other, openings G are made, so as to allow the convergent ends of the hooks to pass through; and by means of the parts F having their edges somewhat of voluted or spirally-inclined form, when the pipes A and B are placed in such relative position that the hooks E have passed through the openings G, it is only necessary to partially rotate one or the other of the pipes to cause them to be properly joined.

CARBURETTING GAS-LAMPS.—Kitson, A., of Philadelphia, Pa., U.S.A. No. 10,043; July 10, 1888. [8d.]

This invention is particularly adapted for enriching a heavy combustible gas with the vapours of solid crystalline hydrocarbon.

Heretofore (says the patentee) in enriching gas-lamps, where solid hydrocarbons have been used, it has been customary to liquefy the top layer of the hydrocarbon in the vessel, by conveying heat to it directly—by the heated gas, by conduction by means of heated metal inserted in the material, or by liquefying the entire mass of hydrocarbon in the vessel; whilst the gas requiring to be enriched has hitherto been brought in contact with the top layer of hydrocarbon, where it has mixed with the volatilized matter. Considerable time also must always elapse after lighting the burners, before the process of carburation commences; and in cases where the gas pressure has been very low, the process has failed to act completely, while with a consumption of less than 3 feet per hour, no lamp hitherto constructed has been able to operate successfully. Again, says the patentee, while it is quite desirable to enrich low-grade combustible gases (such as producer gas, or mixtures thereof with water gas) for illuminating purposes, it has been found impracticable to accomplish this object with the carbureting attachments now in use, since they are constructed to conduct gas up to the burners from the carbureting vessel, and are for enriching coal gas requiring only a small addition of illuminants. Coal gas possesses sufficient affinity for the vapours of naphthalene used in these lamps, to carry the proper proportion thereof up to the burners; but producer gas is not only almost without illuminating qualities, but contains a comparatively large percentage of nitrogen and other heavy gas, which have no affinity for the hydrocarbon vapours, and will not, therefore, be enriched in the ordinary lamp to a sufficient degree to yield, in combustion, the necessary illuminating power.

The object of the present invention is, therefore, to provide means (in addition to the gas itself) for conducting hydrocarbon vapours directly into the burner tube and down to the burner; also to provide a method of carburation which will operate effectively with every kind of combustible gas, which will work well on very low gas pressures, and which will carburet a small as effectively as a large quantity of gas. Another object is to simplify the construction of the lamp, make it compact and convenient to manipulate, and further to provide for quickly starting the carbureting operation after lighting the gas at the burner.

According to one plan of operation, the bottom layer of crystalline hydrocarbon is caused to be liquefied by heat; and a thin stream of the liquid is conducted by gravity into a tube or chamber, containing a capillary material, which is heated by the flame of the burner, and through which the gas to be enriched or carburetted passes on its way to the illuminating burner. In this chamber, leading to the burner, the liquid becomes instantly vaporized by the heat; and the resulting vapour is carried on down to the burner. According to another plan of operation in connection with a slightly modified construction of lamp, provision is made for melting a portion of the solid hydrocarbon, and conducting the liquid by a fibrous capillary conductor into the heated descending tube, wherein the vapours given off from the capillary conductor mingle with the gas to be enriched, and flow readily therewith down to the burner. As soon as the burner is lighted, the small amount of hydrocarbon lodged in the vaporizing chamber, or the capillary conductor in the burner-tube, is vaporized; and the carbureting operation immediately commences.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

SPIRAL-FRAMED GASHOLDERS.

SIR,—In the last issue of the JOURNAL, a correspondent has described a discovery he has made of a special variation of my invention of the spiral-framed gasholder for dispensing with the external or upper framing altogether. In this rather obvious variation, your correspondent proposes to simply reverse the method described by Mr. Newbigging in his paper read at Doncaster, on the 25th of August last, by which act that gentleman voluntarily did me a great kindness, in a very masterly manner.

I quite agree with your correspondent as to the possibility (and perhaps, in some cases the advisability) of so proceeding with my invention; only, unfortunately for him, his suggestion is somewhat late in the field, as I have described that and other variations in the specification filed in the Patent Office, and which is now accepted. I send you herewith a copy of this specification wherein you will find the particular variation referred to by your correspondent.

There are other variations, which may prove interesting, even if they be not often employed. But they may nevertheless anticipate those ingenious attempts which are often made to evade a patent, and thus open up the possibility of obtaining the results of great study, labour, and cost, without involving the necessity of paying the inventor or his enterprising associate the legitimate reward for the same. I say this, however, without in the slightest degree imputing any such motive to your frank correspondent.

Manchester, Sept. 13, 1888.

W. GADD.

GAS ANALYSIS.

SIR,—I am obliged to Mr. Whieldon for his criticism of my article on the above subject. Stated shortly, he says:—(1) Is not the gas-bottle too large? (2) Is not the surface exposed to the confining liquid more with this bottle than with a smaller one? (3) Can percentages above 25 per cent. be determined? (4) Does not the gas-bottle closely resemble Mr. Wanklyn's? (5) Are the connections of india rubber? (6) Are not the solutions exposed to the air for a considerable time? (7) Are not the injurious solutions sucked off by the mouth? (8) The solutions are similar to Professor Wanklyn's? (9) The gas, when tested for ammonia is exposed to the absorbing influence of water; and in the test for sulphuretted hydrogen, it is washed and the washings lost. (10) Why is naphtha preferred to bromine and fuming sulphuric acid? (11) Is potash or ammonia used for titrating sulphuric acid? (12) It is difficult to read absorption. (13) Corrections for temperature and pressure would be erroneous where the gases are estimated by absorption. (14) Can hydrogen and marsh gas be tested for by this bottle?

In reply I may say: (1) The size of the bottle is of little importance so long as it is not unwieldy. (2) The surface exposed to the confining liquid is not greater in proportion to the gas present than with a smaller bottle. (3) I might have added that, for percentages above 25 per cent., a separate measure is required, connected in the same manner as the burette shown at M [see sketch given with article]. The water-lines should be equalized by raising or lowering this measure. (4) If my gas-bottle very much resembles Mr. Wanklyn's, surely it does not detract from its usefulness. (5) The connections are made of indiarubber tubing; and there is no difficulty with them. (6) The solutions are not exposed to the air for more than two minutes. The burette is only used when it is necessary to measure the solutions. (7) If it is necessary to suck off the injurious absorbents, then an aspirator of some kind can be used. (8) The absorbents used by me are not new; but they are not in general use. (9) The gas is only exposed to the surface of the water for a very short time. I think Mr. Whieldon must have misread the test for sulphuretted hydrogen. (10) I prefer naphtha because it is not nearly so injurious as bromine and fuming sulphuric acid. (11) Either potash or ammonia can be used; but I prefer ammonia. (12) The bottle is held in the stand, and can be lowered into the trough with great ease; and if the trough is placed on a level stand, the bottle must be vertical. (13) The bulk of the gas should certainly be corrected to standard temperature and pressure, as well as the results obtained by absorption. (14) I should think hydrogen and marsh gas might be tested for by this bottle; but I have not yet done so. Will Mr. Whieldon explain what he means by "at a slight under-pressure."

In conclusion, I would say that this class of bottle, although not absolutely accurate, is found to be sufficiently so, and is very convenient for all tests made on the works.

WILLIAM G. HICKS.

Ramsgate, Sept. 14, 1888.

OBLIGATIONS OF THE CHAIRMEN OF GAS COMPANIES.

SIR,—Kindly spare me space for a brief notice of the article in the *Financial News* (which you have reproduced) on the subject of my letter to you hereon.

While thoroughly endorsing my views in general, the article misquotes my statement. The *Financial News* makes me say that "the cost of coal was lower in the half year immediately preceding the period which the Chairman was discussing, as well as in the half year ending June 30—a period to which Colonel Makins made special reference." This is sheer nonsense. If the "cost of coal" had been lower at the two antecedent periods referred to, there would have been no reduction, but, on the contrary, an increase. My statement was (as shown by the figures) that the "reduction" in the net cost of coal had been exceeded in the two previous half years—which is a very different thing. That the *Financial News* should have committed such an error is, to me, quite as startling as was the subject of my remarks.

Surely such an authority should have figures at their fingers' ends, and not be obliged to fall back upon the halting device of saying "if the statistic is right." I can only conclude that the "calculating boy" of the *Financial News* was incapable of finding the differences respectively, between 78-55d. and 63-82d., 76-08d. and 62-54d., and 63-82d., and 53-38d. (the figures for the June half years of 1886-7-8, and the December half years of 1886 and 1887), and of seeing for himself that

14.73d. and 13.54d. were greater than 10.44d.—all these being arrived at by simple subtraction. Otherwise the *Financial News* must have taken my figures, without verification, upon the principle that any stick is good enough wherewith to beat a dog.

Further the *Financial News* is good enough to regard me as a shareholder in the Chartered Company whose wits and memory were too defective to permit me at the meeting to catch the Chairman tripping—notwithstanding my distinct disclaimer. If that were true, my statements would have no weight at all in support of its own views. As a matter of fact, when I wrote to you, I had never either seen or spoken to the Governor of the Chartered Gas Company, nor yet to the Chairman of the South Metropolitan or any other Gas Company, to my knowledge. I am in the strictest sense of the words, a typical "Outsider," as I am not a shareholder in any Company whatsoever. *Pace the Financial News*, therefore, I still claim to be neither more nor less than what I have signed myself—to wit, an

OUTSIDER.

THE EDGERTON PHOTOMETRICAL SLOT.

SIR,—In your issue of July 24, under "Notes," you describe an "Edgerton" slot-chimney, and say: "It is admitted that the principle of the Edgerton standard is identical with the Methven standard, which must have suggested it." I think you are in error as to the Methven slot suggesting the Edgerton standard. I believe that Mr. Edgerton antedated Mr. Methven in the use of an opaque chimney with slot, for testing gas against itself.

In 1877, in the New Orleans Gas-Works, I used this standard myself; it having been prepared by Mr. Edgerton. He tells me that his first burner with an opaque sleeve, with slot over the chimney, was made in 1875; and I have in my possession a photograph of it, taken in that year.

Mr. Edgerton has told me that in 1875 he exhibited the standard at the meeting of the American Gaslight Association, in New York, at which, I believe, Mr. D. Bruce Peebles, of Edinburgh, was present.

I respectfully request that you will give this correction a place in your columns.

Philadelphia, Aug. 30, 1888.

WALTON CLARK.

INQUIRY CIRCULARS AGAIN.

SIR,—The following questions were sent to me in a circular form without even a stamped envelope for reply:—

1. Do you, in supplying the return of the profits of your gas-works, make a deduction in the assessment for gas used by the Corporation for public lighting purposes?
2. Do you make a deduction for depreciation of plant and machinery apart from, and in addition to, the annual outlay for repairs and maintenance of works.
3. What is the rate per cent. on the value of the plant and machinery you deduct for depreciation?
4. What descriptions of gas apparatus, plant, and machinery, do you include in the valuation upon which the deduction is based?

I hope that, as circulars of this description are received, they will be exposed before being consigned to the waste-paper basket; so that professional men who understand their business may have a fair chance of continuing to earn their living.

Sept. 12, 1888.

ENGINEER.

SMALL-BORE WATER-METERS.

SIR,—I notice a large number of $\frac{3}{4}$ -inch water-meters are offered for sale by one of the Corporation Water-Works in England. Being interested in the use of small meters, it would confer a benefit, not only on myself, but many of your readers, if interchange of opinion might be obtained through the *JOURNAL* on the merits of employing small-bore meters. I see the last patent applied for a water-meter is supplied by a $\frac{1}{2}$ -inch service-pipe; and these are about to be introduced into a foreign water-works for the general supply to the inhabitants. My own experience of $\frac{1}{2}$ -inch meters proves that, with moderately hard unfiltered water, the $\frac{1}{2}$ -inch apertures, and the small working parts, soon become corroded—rendering so small a machine useless.

MAINS.

THE SUPPLY OF OIL GAS AT COLINSBURGH.—"Utility" (whose letter on this subject was published last week, with an editorial note appended to it) writes to justify the opinion he gave of the "news article" which appeared on page 427 of the *JOURNAL* of the 4th inst., to the effect that it was of our own construction and "somewhat prejudicial to the gentleman whose name was freely used therein." Our correspondent writes: "The 'article' begins by referring to your readers as *our readers*; and next, you say there has been 'communicated to one of the Edinburgh newspapers,' 'results,' which you do not give. But you go on to 'broadly' give your deductions from those results, elsewhere reported; and, in doing so, you place the unsupported testimony of an ordinary unskilled gas consumer against the tabulated facts and experience of a gentleman who has by force of circumstances made oil-gas manufacture and distribution a practical study, and, further, one who, being a lawyer and banker, his judgment and figures are entitled to the respect usually accorded to an intelligent mind." The word "broadly" (in connection with the deductions from the experiments in question) was made use of in the original correspondence by Mr. Dawson—the very gentleman whose cause our correspondent is taking up; and who, it may be remarked, has evidently not been misled, as "Utility" would have us believe that he has been, by the way in which the communications to the Scotch newspapers were referred to in our columns.

THE WALSALL GAS UNDERTAKING.—At the meeting of the Walsall Town Council on Monday last week, on the recommendation of the Gas Committee, authority was given to raise £5000 of additional capital for the purposes of the gas undertaking, and towards defraying the cost of the new gasholder and tank.

Legal Intelligence.

HIGH COURT OF JUSTICE—CHANCERY DIVISION.

WEDNESDAY, SEPT. 12.

(Before Mr Justice DENMAN, Vacation Judge.)

BLAKER V. HERTS AND ESSEX WATER-WORKS COMPANY, LIMITED.

Mr. INGPEN, appearing for the plaintiff (who sued on behalf of himself and all other debenture holders in this Company), to-day moved for the appointment of a Receiver and Manager of the undertaking of the defendants. In 1883, the Company issued debentures to the amount of £6250; these being a first charge upon the undertaking, land, works, plant, property, and effects, both present and future of the Company. The principal of each debenture was payable on July 1, 1888, and interest at the rate of 5 per cent. half-yearly; but default had been made in payment of the principal, and one-half year's interest was in arrear. The whole of the share capital had been fully paid-up; and it was necessary, in order to carry on the undertaking, that the Company should obtain large advances of money. In 1885 an Act was passed extending the borrowing powers of the Company by an issue of £12,250 of debentures. This power the Company was desirous of exercising; but, of course, they could not give a prior charge to that of the plaintiffs, who refused to assist in the carrying out of the arrangements for obtaining fresh capital.

Mr. BRAY, who appeared for the Company, said he was willing to consent to the appointment of a Receiver.

Mr. INGPEN said he was instructed to ask for the appointment of a Manager as well as a Receiver. The Company had suggested that the debenture holders should exchange their debentures for those of the new issue. But this proposal had not been acceded to; and the Directors had sent out a circular in which they stated that nothing could be done unless the existing debenture holders would exchange their debentures, and that the only alternative appeared to be the winding up of the Company, as it was impossible to go on with the business without more plant and money. As the Company could not carry on its business, the debenture holders had a right to take possession, and carry on the concern with a view to protect the property over which they had a first charge. Under these circumstances, he asked for the appointment of Mr. Evans as Receiver and Manager.

Mr. BRAY submitted that it was not the practice of the Court to appoint a Manager.

JUSTICE DENMAN pointed out that the Directors had admitted they could not carry on the business of the Company.

Mr. BRAY suggested that the Secretary should be appointed, in which case the expenses would be considerably reduced.

JUSTICE DENMAN said he was of opinion that the plaintiffs were entitled to have a Receiver and Manager appointed; but the proper course was to refer the matter of the appointment to chambers, and this he should adopt.

DAMAGE TO WATER-MAINS BY A THUNDERBOLT.—During a fearful thunder-storm which raged over Toulon and its environs on the night of the 25th ult. a thunderbolt fell upon the buildings of the General Water Company, which are situated about three-quarters of a mile from the city. It penetrated into the principal main of the town as well as into the two mains for serving the town of Seyne, which are both on the road to Dardennes. The large reservoirs below were completely emptied, on account of the bursting of the great central pipe; and the water precipitating into the valley has caused considerable damage.

KESWICK GAS COMPANY.—The report of the Directors of this Company which, with the accounts for the year ending June 30 last, was submitted to the shareholders at their first ordinary general meeting after the passing of the Company's Act (which received the Royal Assent on the 28th of June), held on the 4th inst., stated that there was a balance to the credit of the profit and loss account of £732, which, added to £347 brought forward, made a sum of £1079 available for distribution. A dividend at the rate of $\frac{6}{11}$ per cent. per annum was declared, and a bonus of 1 per cent. per annum added. This absorbed £618; leaving a sum of £461 to be carried forward.

AN ELEPHANT IN A GAS-WORKS.—A large elephant, belonging to Messrs. Sanger and Son's circus, temporarily stationed at St. Ives, Hunts, broke out of its quarters last Thursday morning, and committed a great deal of damage. It broke down two or three gates and some fencing, demolished a brick wall, and entered the premises of the St. Ives Gas Company, where, by withdrawing a plug, it wasted about 2000 feet of gas. Finding its way to the retort-house, it gave the man in charge a tremendous scare; and he lost no time in placing a good distance between himself and the unwelcome visitor. After doing considerable damage in the neighbourhood of the works, the animal was captured with some difficulty, and taken back to the circus.

STOCKTON AND MIDDLESBROUGH WATER SUPPLY.—At the meeting of the Stockton and Middlesbrough Water Board on Monday last week, the annual accounts of the Board, which were presented, showed that the total expenditure, exclusive of rent, rates, and taxes, had been £7625 18s. 11d. which was a considerable decrease as compared with previous years. The cost of pumping per 1000 gallons during the current half year, exclusive of uncontrollable expenditure in the shape of rates and taxes, has been 0.579d., or a decrease of 0.081d. on the cost under the Company in 1874-5. The usual report from Mr. J. Mansergh, the Board's Engineer, was submitted, showing that satisfactory progress was being made at the Hury reservoir, and the various other works in course of construction.

NORTHERN COAL TRADE.—The condition of the steam-coal trade does not show great variation during the last few days; the price being maintained at about 7s. 6d. for best Northumbrian qualities. Small steam-coal is abundant, and the price is weak. In the Durham coal trade there is considerable activity. As expected, the Newcastle gas-coal contract has been placed at an advance which may average about 3d. per ton. Some parts of it have been given out at last year's average rate; but on the whole it may be said that the price is now 6s. 1½d. delivered. But this is not a very high rate; and if it be supposed that the railway carriage averages 6d. per ton, it will be seen that the coal-owner does not obtain a very large price. Gas coal is increasing in demand with some rapidity just now; and there are all the indications of a good season's trade. Many of the leading contracts for this class of coal are now fixed, and some of the most important collieries have about booked the extent of their output; so that it is possible the prices will be dearer for the coal that is not contracted for. Manufacturing coal is now being arranged for for next year; and most of the works which use Durham coal have had to pay from 3d. to 6d. per ton more than the last time of contracting. In some other branches the coal trade shows an improving tendency. Household coal, however, is an exception; and the finer weather will further depress this class of coal.

Miscellaneous News.

THE CHARGES AGAINST THE HALIFAX GAS-WORKS OFFICIALS.

RESIGNATION OF MR. W. CARR.

It will be remembered that at the meeting of the Halifax Town Council on the 5th inst., as reported in the JOURNAL last week, the Corporation Gas Engineer (Mr. W. Carr) was called upon to take proceedings against the *Pall Mall Gazette* for the statement made in the columns of that paper in June last in regard to the coal contracts of the Corporation, or to send in his resignation. It was stated in a paragraph at the end of our report that, according to the Halifax Correspondent of the *Bradford Observer*, Mr. Carr had decided on adopting the latter course. As will be seen by the following correspondence, which has been forwarded to us for publication by Mr. Carr's Solicitors (Messrs. Storey, Bedford, and Willans), this statement was correct. In asking us to insert the letters, Messrs. Storey say they may "confidently appeal to the public to suspend their judgment in the matter for the present, and wait until they have furnished to them something more solid and reliable than mere innuendo."

[ENCLOSURES.]

Keighley Walton, Esq.

Halifax, Aug. 31, 1888.

Dear Sir,—Both before and since our Mr. Storey's conversation with you and the Mayor this morning, we have given our best consideration to the proposal made by the Committee that our client, Mr. Carr, should commence an action against the proprietor of the *Pall Mall Gazette* for libel. As our Mr. Storey stated to you, we have all along advised our client that an action would not lie; and in this we are borne out by the very opinion of Counsel which you have taken on behalf of the Corporation. This being so, we fail to perceive what good could be done by taking proceedings which must inevitably prove abortive. Our client is prepared to meet any direct charge which may be formulated; but he would be wanting in self-respect were he to take umbrage at a paragraph in a newspaper which points at no one particularly, and should therefore be treated with supreme indifference. If there is anything which can be said to reflect unfavourably on our client's conduct as the Corporation's Gas Manager, let it be known, and, if untrue, it shall be met at once; or if there is any charge to be made, let our client have the particulars, and he will then be in a position to meet his accusers face to face. This is the position he takes; and sooner than depart therefrom, he would prefer tendering his resignation to the Council, to be dealt with as, after due consideration, may be thought advisable. We think, in the course we have taken, we have advised our client for the best, and do not hesitate to accept any responsibility which may consequently rest upon us.

(Signed) STOREY AND CO.

Keighley Walton, Esq.

Halifax, Sept. 5, 1888.

Dear Sir,—This matter [the "gas scandal"] is, we understand, to be discussed in Committee (Council) this evening. Should the necessity arise for our Mr. Storey to attend before the Committee for the purpose of explaining our client's position, he will be ready to do so.

(Signed) STOREY AND CO.

Keighley Walton, Esq.

Halifax, Sept. 12, 1888.

Dear Sir,—Our client, Mr. Carr, has conferred with us in reference to the resolution of the Council passed on the 5th inst., calling upon him either to commence an action against the *Pall Mall Gazette* or resign his position as Gas Manager. Notwithstanding all that was advanced in alleged justification of the course the Council were taking, our client is still advised that no action can possibly lie against the proprietors, printers, or editor of the *Pall Mall Gazette*; and therefore to commence the proceedings required by the Council is out of the question. We addressed a letter to you on the 31st ult., which we are surprised to find was not communicated to the Council, and consequently could not be taken into consideration by the members of that body. Further than this, although you knew our Mr. Storey was prepared to attend before the Council, for the purpose, if necessary, of explaining our client's position, he was not called upon, but excluded from the Council Chamber during the discussion; thus leaving our client practically unrepresented. Under these circumstances, and for the reason given in our letter to you, our client has no alternative left him but, through us, to resign his position as Gas Manager; this being the only dignified course a man of Mr. Carr's position and reputation can take. In accepting the alternative given him, our client reserves to himself the right of enforcing against the Corporation such claims as the action of the Council may enable him to make.

(Signed) STOREY AND CO.

Town Clerk's Office, Halifax, Sept. 13, 1888.

Messrs. Storey, Bedford, and Willans, Solicitors.

Dear Sirs,—I am in receipt of your letter of yesterday's date. Your letter of the 31st ult. was handed to the Mayor, who used his own discretion as to its being read to the Council. You are mistaken in stating that I knew your Mr. Storey was prepared to appear before the Council. I did not receive your letter until after the close of the Council meeting; but I am authorized by the Mayor to state that such a course would not have been permitted.

(Signed) KEIGHLEY WALTON.

Keighley Walton, Esq.

Sept. 13, 1888.

Dear Sir,—We note the contents of your letter of this morning, which, with copies of our letters to you, we propose inserting in the newspapers, so that the public may know the exact position our client, Mr. Carr, has taken.

(Signed) STOREY AND CO.

The following paragraph appeared in the *Bradford Observer* last Friday:—"It is now generally expected that the Mayor will, as soon as practicable, sign the indemnity to Mr. Thomas King Fox, of the Silkstone Colliery Company, near Barnsley; and Mr. Fox will then forthwith, according to the terms of the indemnity, give the names and addresses of the persons against whom he alleges malpractices, together with details and particulars of such charges. There is a considerable undercurrent of sympathy in the district with Mr. W. Carr, and the ratepayers are very loud in expressing their opinion that the matter should be sifted to the bottom, and that Mr. Carr's resignation should not in any sense be allowed to operate to the advantage of other persons against whom malpractices are alleged, and who, it is understood, are quite equal financially to the task of vindicating their characters and reputations."

CRYSTAL PALACE DISTRICT GAS COMPANY.

The Ordinary Half-Yearly Meeting of this Company was held last Friday, at the Albion Tavern, Aldersgate Street, E.C.—Mr. FREDERIC LANE LINGING in the chair.

The SECRETARY (Mr. Magnus Ohren, Assoc. M. Inst. C.E.) read the notice convening the meeting; and the Directors' report and the statement of accounts, an epitome of which appeared in the JOURNAL for the 4th inst., were taken as read.

The CHAIRMAN in moving—"That the report of the Directors and the balance-sheet, examined and signed by the Auditors, be received, adopted, and entered on the minutes," said that the Directors entertained the hope that the results of the past half-year's working had met with the shareholders' approval; for not only had they been enabled to earn the dividends upon the whole of their capital, but were able to carry the sum of £3686 to the next half year. The figures in the accounts stood somewhat thus: Their profit, including the interest upon the reserve fund, amounted to £17,311, and the dividend would absorb £13,625; leaving the balance he had mentioned to be carried forward. This balance, added to that brought from the half year ending Dec. 31, 1887, gave them an available floating asset of very nearly £5000; and therefore the Board thought they were supported in the announcement of a further reduction in the price of gas to 2s. 8d. per 1000 cubic feet, to take effect from the close of the present quarter. Should the coal dues cease to exist in the course of next year, there would come to the revenue of the Company a sum more than sufficient to enable them to lower the price to 2s. 7d. per 1000 cubic feet. This asset, which the Board hoped would be realized, would, in their particular case, go to the gas consumer, because, as the shareholders were aware, by the Acts of the Company they had no sliding scale; and therefore they were unable to raise the dividend as they reduced the price of gas. Perhaps it might not unfairly be assumed that the shareholders indirectly benefited by these reductions, because lowering the price of gas necessarily stimulated consumption. Increased consumption, of course, required more plant; and this additional plant compelled the Directors to call upon the shareholders to provide the money to enable them to carry out the work. Thus he considered that indirectly the shareholders benefited to a certain extent. Perhaps in the history of gas manufacture there never was a time like the present when it was so advisable for those who had the control of gas interests to endeavour to reduce the price of gas to the lowest possible point; and he knew full well that the directors of gas companies and their chief officers were imbued with this feeling, and he knew they had exerted themselves in every possible way to carry it out. They need not be at all alarmed at electricity or those cheap oils which were coming into competition with gas. At the same time, he thought it would be sheer folly for them to ignore the fact that the electric light was now a light of continuity, which it had not been up to within a recent period. But it was a costly light; and therefore only within the control of those who were indifferent to the expense. As regards petroleum, however, this he knew was coming into competition—not so much perhaps in the Metropolis as it was in the provinces, to his knowledge. Although he alluded to these things—and it was well to keep them in sight—he had unbounded faith in gas. He believed it would maintain its position, and continue in that healthy prosperity which now surrounded it. Upon a former occasion, when he had the privilege of addressing the shareholders, he referred to their coal arrangements; and he did so because coal was necessarily of very vital importance to the Company. He then mentioned certain savings the Board had been enabled to make; and he was glad to say he could continue upon this score, and now announce that they had effected a further saving in the cost of the coals in the shape of freight. With the shareholders' permission, he would take the two previous years, and compare them with the present half year. Their coals cost them in the year ending December, 1886, 15s. 14d. per ton; and for the year ending December, 1887, 14s. 5½d.; but for the half year under consideration they had only cost them 13s. 11d. He did not know whether they would be able to effect another saving under this head; but the shareholders might be assured of this, that if they could do so they would. There was one paragraph in the report that he should like to briefly dwell upon—that was the one in regard to the retirement of Mr. Henry Palfrey Stephenson from the chairmanship of the Company. Mr. Stephenson unhappily had been declining in health for some time; and there was no doubt that, had his own wishes been consulted, he would have retired from the chair some twelve months or more ago. But out of deference to the expressed desire of his colleagues, he consented to continue in the office until the spring of this year, when the time came for the re-election of the Chairman for the following year. Mr. Stephenson appealed to the Board in very strong terms, and begged them not to nominate him to the position, as his health was such that he could not possibly undertake its duties. Most reluctantly they consented, but asked him to take upon himself the duties of Deputy-Chairman; and this he agreed to do. As Mr. Stephenson was not there, it would not be deemed bad taste on his (the Chairman's) part if he made a little further allusion to him. He might state to those gentlemen who were unacquainted with the early history of the Company, that Mr. Stephenson was one of its first Directors, and Dr. Hetley was another. There was no doubt that Mr. Stephenson in those early days placed the Company upon a solid foundation; and he had shown an amount of energy and loyalty to its interests which he (the Chairman) did not hesitate to say, had never been surpassed. His intellect, happily for him was as strong as ever. He need not say how gratified they were as Directors to know that they would retain the services of one whom they so esteemed and respected. Turning to the accounts, he said he did not know that he need take up much of the shareholders' time in referring to them. However, he would just allude to one or two matters of interest. As to coals, they had in this item a saving of £773, as compared with the corresponding period of last year; and then on the credit side of the account they had an increased rental of £1622. The other items on the debit side of the account were such as would necessarily vary; and they did so in this half year. Under the head of repairs to retorts, &c., there was certainly an increase of something like £700. Most of those present were well acquainted with gas matters, and were aware that in a gas-works it was impossible to get these amounts the same half year by half year; and therefore there was an increase in the six months under review. This also applied to meters, stoves, &c. With these exceptions, there were no items he need allude to on the debit side of the account. When he turned to the credit side, under the head of residual products, they would find that coke was £2565 in excess of the corresponding period of 1887. Sulphate of ammonia and ammoniacal liquor had also increased by £342. These two items made a sum of nearly £3000; and he was pleased to state that they had not had such results under the head of residual products for some time past. The coals carbonized had increased by 1125 tons; and they had sent out 12,380,000 cubic feet of gas (or equal to 3.63 per cent.) over the corresponding period of last year. The Directors were anxious about this matter; and they had hoped to show a better result. They believed they would do so in the present and future half years. As the shareholders were aware, the Company's district was a residential one,

with a large number of excessively high-rented houses. Many of these had been untenanted, from circumstances which the shareholders could quite understand. But the houses were now letting at lower rents; and therefore as the tenants came in, so would the Company receive some benefit. Their capital per ton of coals carbonized was as healthy as previously. It was only £4 16s. 7d. The gas unaccounted for over the half year was only 2·30 per cent. Among those present were gas engineers of eminence, who he was sure would appreciate the working of the Company's Engineer (Mr. C. Gandon, M. Inst. C.E.) during the half year.

Mr. GEORGE LIVESY seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed—"That a dividend for the half year ending the 30th of June last be now declared, at the following rates per annum:—viz., 6 per cent. on the preference stock, 7 per cent. on the ordinary 7 per cent. stock, 10 per cent. on the ordinary 10 per cent. stock, and 7 per cent. on the new ordinary 7 per cent. shares, all less income-tax, and that the warrants for the same be forwarded by post to the proprietors, or their authorized agents, on or before the 21st inst."

Mr. JAMES GLAISHER, F.R.S., seconded the motion, which was agreed to.

Mr. HORATIO BROTHERS moved the following resolution:—"That the thanks of the meeting be given to the Directors for their able management of the affairs of the Company." He remarked that he was sure all those who had heard the lucid statement of the Chairman must have come to the conclusion that the works had been very ably managed during the past half year. For a district like theirs, which extended over a very large area, it was astonishing to him, as an old gas man, to learn that the leakage was only 2½ per cent.

Mr. LIVESY: The average is 4·5 for the year.

Mr. BROTHERS said he was speaking of the half year under review. The only thing that struck him was that, in these prosperous times, he hoped the Directors would take care that the works were kept in good order. He also trusted that the Board would treat their officers in a liberal and generous spirit. Their Secretary (Mr. Ohren) was a very able man; and as to their Engineer (Mr. Gandon), he was convinced that they could not have a better one.

Mr. R. HESKETH JONES, J.P., said he had much pleasure in seconding the resolution. As to the remarks of Mr. Brothers, he had to slightly differ from him when he appealed to the Board as to maintaining the works in good order. He (Mr. Jones) thought the half year under review indicated that the Directors had done so, inasmuch as they had expended some £700 additional for repairs and maintenance of works. In speaking of this additional expenditure, the Chairman adopted a somewhat apologetic tone, which he (Mr. Jones) did not think was at all necessary.

The motion was carried unanimously.

The CHAIRMAN, in acknowledging the compliment, observed that if Mr. Brothers would favour them with a visit to the works as an Engineer, he would see that they were in the most perfect state of preservation. The Directors frequently went through the works; and he could assure the shareholders that they would be kept up to the highest degree of efficiency, while care would be taken not to incur any unnecessary expense. Continuing, he moved a vote of thanks to the Auditors (Messrs. A. T. Layton and C. Newton) and the officers of the Company. He remarked that, as there had been a large exchange of stock, in consequence of the Royal College of Surgeons having sold out the shares left to them by Sir Erasmus Wilson, and there might be some new shareholders in the room, he would take the opportunity of letting them know how highly the Board appreciated the services of their officers. Mr. Ohren had been connected with the Company for upwards of 30 years, and a more efficient officer he thought did not exist. Mr. Gandon, their Engineer, came to them with the highest recommendations; and from that time to the present there had not been a single instance when they had to say to him: "Why have you done this; or why did you not do this?" As regards the staff under the supervision of the Secretary and the Engineer, he believed they had as good officers as it was possible for any company to have.

Mr. WESTCOTT seconded the motion, which was agreed to *nem con*.

Mr. C. NEWTON briefly replied on behalf of the Auditors and the other officers of the Company; speaking in high terms of praise of the manner in which Mr. Ohren kept the Company's books.

The proceedings then terminated.

SHEFFIELD UNITED GAS COMPANY.

THE REPORT AND ACCOUNTS FOR THE HALF YEAR ENDING JUNE 30.

The report of the Directors of this Company for the six months ending June 30 last, which, with the accounts, will be presented at the half-yearly general meeting of shareholders on the 1st prox., states that there was in this period a satisfactory increase in the receipts both for gas and residuals, and that the financial position of the undertaking is such that, after the payment of the maximum dividend, and placing £2835 11s. 7d. to the reserve fund, there will be £1138 8s. 11d. to be carried to the credit of the current half year. The Directors recommend the payment of such dividend, which will amount to £6750 on the "A" stock, £10,452 13s. 6d. on the "B" stock, £11,453 10s. on the "C" stock, and £3438 12s. on the "E" shares (£8 10s. each, £6 per share paid); amounting together to £32,094 15s. 6d. The Directors report that the policy of placing meters in consumers' houses, without making any charge for fixing, has been successful. The number of additional meters fixed during the twelve months ending in June last was 1777, against 678 fixed in the previous year. The Board have, as from Oct. 1, 1888, reduced the price of gas in the outlying districts of Dore and Totley to 2s. 2d. per 1000 cubic feet; thus making the maximum price to private consumers uniform throughout the whole of the area supplied by the Company. Under the Sheffield Gas Act, 1886, power was given to raise, by the creation of new ordinary shares, any sums not exceeding in the whole £350,000. This power has up to the present time been exercised to the extent of only £229,070; and the Company can under it still create share capital to the extent of £120,930. The Board recommend that shares of the nominal value of £6 each be created for £120,696, part of the balance, and be offered at par to the existing shareholders, in proportion, as near as may be, to the stocks and shares, or either, held by them. The accounts accompanying the report show that of the £641,895 of capital called up, £633,741 has been expended; leaving a balance of £8154. The amount received for gas and the rental of meters and stoves was £81,409 19s.; residuals produced £26,415 8s. 1d.; and a few miscellaneous items bring up the total receipts to £108,765 13s. 10d. The sum of £58,470 2s. 1d. was expended on the manufacture of gas (£32,787 being for coals), and £4944 16s. 1d. on its distribution; rates and taxes came to £6230 8s. 5d.; and management and miscellaneous expenses make a total of £74,032 13s. 6d.—leaving a balance of £34,933 0s. 4d. to be carried to the profit and loss account. The balance of this account available for dividend is £36,123 16s. The Company's reserve fund now amounts to £64,159. The quantity of coal carbonized was 77,515 tons (12,845 tons being cannel); and the residuals produced were: Coke and breeze, 47,650 tons; tar, 5256 tons; ammoniacal liquor, 2,422,000 gallons.

BRISTOL UNITED GAS COMPANY.

The report of the Directors of this Company, to be submitted to the proprietors at their half-yearly general meeting on the 19th prox., shows that there has been a profit of £30,628 on the working of the undertaking in the six months ending June 30 last, as compared with £21,140 realized in the corresponding period of the past year. There has been an increase in the quantity of gas sold, yielding an additional revenue of £3208. The amount produced by the sale of residual products also shows an advance amounting to £4037; and, by careful economy, a considerable saving has been effected in the expenditure. The Directors remind the shareholders that, with a view to the development of the use of gas for cooking, heating, and motive, as well as for illuminating purposes, a comprehensive exhibition of gas apparatus, containing the most modern appliances, was held in May last, at which lectures illustrative of the use of gas were given daily. As evidence of its success, they mention that upwards of 700 cooking-stoves have since been issued upon hire, in addition to others sold. The Directors record the retirement of their Engineer, Mr. Walter Riddes, after 44 years' service; and say they have awarded him a retiring allowance of £500 per annum. The usual dividend at the rate of 10 per cent. per annum on the nominal capital of the Company entitled thereto is recommended, subject to deduction of income-tax. The quantity of coal carbonized during the six months reported upon was 70,642 tons; the gas made being 672,490,000 cubic feet, of which 615,154,500 feet are accounted for. The residuals produced were: Coke, 48,800 tons; breeze, 6261 tons; tar, 615,354 gallons; ammoniacal liquor, 1,483,180 gallons.

FALMOUTH GAS COMPANY.

The Annual General Meeting of this Company was held on Friday, the 7th inst.—Mr. R. M. TWEEDY in the chair.

The SECRETARY (Mr. R. J. Lukey) having read the notice of meeting, the report and accounts, which were briefly dealt with in the JOURNAL a fortnight ago, were presented.

The CHAIRMAN, in moving the adoption of the report, remarked that the Company had passed through a very eventful year; and there had been many repairs and several important additions to the works. He hoped now that all the heavy work had been finished, that in the future there would not be so many repairs, as the works were now in good condition. The Assessment Committee had sought to raise the assessment on the gas-works; but the Directors could not see their way to paying more, especially as the amount proposed to be added was £200 per year. It had been referred to the County Court Judge (Mr. Morgan Howard) for arbitration; and he had not yet made his award. What was just and right they would pay. Mr. J. W. Buckley had come from Southport to manage their works, and he had had to give considerable attention to improving the retorts and to the repairing of the mains; and when he came to know the district better, he hoped to decrease the leakage, which was much higher than it should be. The profits were not so great this year as last; being £1290, as against £1552. A considerable portion of the alteration was due to the increase in the price of coal; the amount spent being £1825, as against £1581. There had also been an increase in the insurance policy. The amount received for gas had been about £170 more than last year; but the expenditure for repairs and depreciation had been very heavy. They had not written off so much for depreciation this year as they should have done, as they hoped that next year the amount would be less, and then they could equalize matters a little.

Mr. HARVEY seconded the motion, and it was carried.

The CHAIRMAN then proposed a dividend of 5 per cent. for the half year, with a bonus of 6d. per share.

Mr. NICHOLLS seconded the proposition, which was agreed to; an amendment brought forward in opposition to the payment of the bonus being withdrawn by the mover.

The retiring Director (Mr. W. S. Olver) having been re-elected, Mr. W. J. Coward and Mr. S. Tresidder, jun. (the retiring Auditors), were re-appointed to their positions; the last-named gentleman securing 1297 votes against 1252 obtained by Mr. Taylor, who was put forward as his opponent.

A vote of thanks was passed to the Chairman, and the proceedings closed.

BRISTOL WATER COMPANY.—At the meeting of this Company on Saturday, the 8th inst., an interim dividend was declared for the half year ending the 30th of June last on the £25, £20, £6, and £4 10s. ordinary shares, at the rate of 8½ per cent. per annum.

THE QUALITY OF THE NEW GAINSBORO' WATER SUPPLY.—An analysis of water taken from the deep bore-hole at Gainsbro' has recently been made by Dr. Percy Frankland. He finds that the water is palatable, and contains only a trace of organic matter; it is also free from any suspicion of previous contamination with sewage or other refuse animal substances. He says it is a water eminently free from all risk of communicating zymotic disease; and concludes an exhaustive report by saying (1) that as regards freedom from organic matter, and from evidence of animal contamination, it cannot be surpassed; (2) that in its present condition it is very hard, and that after treatment with lime it would still remain a hard water, although the hardness would be thereby reduced to about one-half its present amount; and (3) that the proportion of magnesia contained in it may be objected to, but that this objection could only be justifiably pressed if another water of practically equal organic purity, and containing little or no magnesia, were to be substituted for it. The water contains 35·4° of hardness; 16·8° being temporary, and 18·6° permanent. The quantity of solid matters per gallon is 49·97 grains. The sample was taken at a depth of 1200 feet in the new red sandstone.

SEWAGE WORKS FOR WOLVERHAMPTON.—Last Thursday, the Chairman of the Sewerage Committee of the Wolverhampton Corporation (Alderman J. Gibbons) laid the memorial stone of the new works which are being carried out at the Barnhurst Sewage Farm, near Tettenhall, about three miles outside the town. The works consist mainly of brickwork precipitation tanks, which are being made for the quiescent treatment of the liquid sewage after it has been dealt with by lime. The scheme has been undertaken to prevent a repetition of the expensive claims which have been brought against the Corporation by the owners of landed property lying along the course of the Pendeford Brook for damages caused by the fouling of the watercourse by the entrance into it of unfiltered sewage. The works now under construction will cost about £5630; but the total cost of the scheme will be something like £8300 or more, since part of the project consists in separating the storm water, which will be allowed to flow into the Smethurst and Stow Heath Brooks, which are the natural channels for it. The works consist of excavating some 5300 superficial yards of agricultural land to a depth of 6 feet, and in some portions to 6 ft. 6 in., and the division of the space so excavated into six tanks, each 150 feet by 50 feet, which will be built of Tipton bricks, with walls 2 feet thick, and resting upon foundations of 1 foot or more of concrete and 2 feet of brickwork. Taking the working depth as 5 feet, each tank will hold about 234,375 gallons; and they will be able to treat 2,000,000 gallons of sewage per 24 hours, which is the quantity of the average dry-weather flow on to the farm.

THE GAS SUPPLY OF HASTINGS.

MEETING OF THE GAS COMPANY—THE CORPORATION AND GAS TESTING.

The Half-Yearly General Meeting of the Hastings and St. Leonards Gas Company was held on Thursday, the 6th inst.—Mr. J. BROWN in the chair.

The SECRETARY (Mr. W. B. Young) having read the notice convening the meeting, the report and statement of accounts, an abstract of which appeared in the JOURNAL for the 25th ult., were taken as read.

The CHAIRMAN, in moving the adoption of the report, said the shareholders would recollect that at the meeting last September it was agreed to reduce the price of gas 2d. per 1000 cubic feet from the 1st of January; and, in addition, to pay another $\frac{1}{2}$ per cent. on the whole of the shares of the Company. He estimated then that, even if there were no increase in the working of the Company, if they did not make any more profit than in previous half years, there would still only be a deficiency of £92. As a matter of fact, however, there had been an increase of upwards of 9 million cubic feet of gas consumed beyond that which was consumed in the corresponding period last year. Therefore, instead of being £92 to the bad, they were nearly £1800 to the good. The receipts were nearly £2000 more than for the corresponding six months of 1887; and so they had not to trouble themselves about any deficiency, but could carry forward a large amount to the reserve fund. The profits on the residuals had likewise increased to the extent of £766. Therefore, the question came again before them: What were they to do with the additional profit. The Directors had come to the conclusion that, as the profits continually increased almost in arithmetical progression, they should do something with the money instead of putting it in the reserve fund; and they decided that the time had come when they might further reduce the price of gas. They had determined, from the 1st of January next, to lower the price another 2d. per 1000 feet. While this would carry an extra $\frac{1}{2}$ per cent. profit to the shareholders, he should like to point out that it was the gas consumers who obtained the greatest advantage. When 2d. per 1000 feet was taken off the price of gas, it represented nearly £1200; whereas the increase of dividend only amounted to £400. One matter to which he wished to call their attention was the way in which a great many people compared the Hastings Gas Company with other companies as to the amount of dividend declared. But in these matters they must take each company on its own footing, as there were many ways in which one differed from another. One of the principal features in the case of the Hastings Company was the large amount which had to be paid as duty to the Corporation, and which amounted to about £3200 a year. If the Company could get rid of this, they would then be quite able to reduce the price of their gas 3d. per 1000 cubic feet. There was, he believed, scarcely a case in the country in which the raw material of manufacture was taxed to the extent of 45 per cent. on the prime cost. There was another point about the coal duty to which he desired to draw their attention. It had been going on for some time; but he could not find out anything about the origin. They had to pay 2s. 5½d. a ton on the coal brought in; but they only received 1s. 8d. a ton for coke taken out. He had been to the Town Clerk about it, and also to the Collector of Coal Dues; and they could not say anything as to why it was so. If they paid 2s. 5½d. when coal was brought in, he thought they should receive the same amount when it was taken out. As it was, they lost 9½d. on every ton of coal they sent out of the town, and this was a very serious drawback. It placed them at great disadvantage when competing with coal merchants outside the town. The proprietors would perhaps remember that in London an agitation had been going on against the coal duties; but there it was only a question of 1s. 1d. It would make a great difference to the Hastings Gas Company if the coal duty in the town could be got rid of. There was another point, and that was the testing of the gas. They were well aware that the Corporation had lately taken up the case of the consumers, and had appointed an inspector of their own to test the gas. He objected to the conduct of the Corporation in this matter. If the Council had the interest of the consumers at heart, and brought a man down to Hastings, the least they could do would be to publish the reports, and let people know what he said. But the Corporation had not done so. Because the report was a good one, they kept it quiet. If it had been a bad one, the report would very soon have found its way into the papers. It had been kept till the 27th of June, and not published. He did not think this was fair. The Council wanted to get a second report, to see if it was a bad one; but, as it happened, it was better than the first. Still they had not published it. He, however, should do so. He had the reports in his hand, and he was going to read from them. That of the 27th of June stated that the illuminating power of the gas was 15·53 candles; the standard of the Company being 15 candles. The sulphur was 11·6 grains, whereas the Act allowed 25 grains. The ammonia was 1·4 grains. The report also stated that there was a slight trace of sulphuretted hydrogen. He strongly objected to this. Mr. Botley, the Engineer and Manager, and the other analysts in their employ said that there never was a trace of sulphuretted hydrogen; and tests had been made for some months past, and yet no trace could be found. The Corporation Gas Examiner, however, had been clever enough to find it. But he (the Chairman) maintained that this gentleman did not test the gas fairly; for he left the test-paper for sulphuretted hydrogen in the gas for 20 hours, whereas the Act of Parliament stated that it should only be left in for three minutes. The report for the 28th of August had not yet been published. It showed that the illuminating power was 15·41 candles; the sulphur, only 9·8 grains; and the ammonia, 0·6 grain. This was almost nothing; and there was no trace of sulphuretted hydrogen. He thought that, so far as the Company were concerned, they had come triumphantly out of the test. He did not think, however, that the Corporation had acted fairly in keeping back the reports instead of publishing them. It was a public matter; and the results should be made known.

Mr. STUBBS (the Mayor) expressed the opinion that the Chairman had gone a little out of the way to attack the Lighting Committee of the Corporation. As far as the Council were concerned, they were willing, on behalf of the inhabitants of the borough at large, to appoint a gas inspector, as they felt that it would be for the public benefit. There was nothing to compel them to publish the inspector's reports; and they only waited for the money to enable them to do so. Personally he thought they should be published. With regard to the coal dues, that was a very difficult question, but he did not think Mr. Brown's arguments would carry weight. It was a great benefit to the town that there should be coal dues; and if the money was not raised in this way, it would come out of the rates. It was a question for all to consider whether it was not an advantage that there should be some revenue from coal. What was left after the manufacture of gas was really a profit to the Company; and therefore he thought the shareholders should not grumble because they had to pay. As to the reserve fund—

The SECRETARY: It is a floating balance.

Mr. STUBBS agreed that it was; but he said he should like to see it in a rather better position. Floating balances varied from day to day. The shareholders could not, he thought, see from the balance-sheet where it was, or that it was in such a position that they could draw a cheque

on it. It would be much better, in the next accounts, to show of what the balance consisted, so that it might be put in tangible shape. He had great pleasure in seconding the motion for the adoption of the report, which he should like to be put a little more clearly.

Mr. WALTER observed that the report was drawn up in accordance with the Act of Parliament. If the shareholders cared to take the trouble, they could learn from the balance-sheet the position of the Company. Nobody could be dissatisfied with the report. Dividends of 6½ and 11½ per cent. were paid; and there was to be a reduction in the price of gas next January. Whether or not it would be possible to grant the consumers any greater concession in price, the Chairman knew better than he did. The reduction promised was a small matter, seeing that they had £23,000 to deal with. He thought it extraordinary that the duty paid by the Company on their coal should be nearly half its prime cost; but he considered that, on the whole, the shareholders might congratulate themselves on the position of the undertaking.

The CHAIRMAN (referring to the remarks of the Mayor) said he thought that if his Worship had looked into the accounts, he would have seen that they were audited, and that the balance-sheet showed all about the reserve fund.

Mr. STUBBS: I want it shown in a more tangible form.

The report was then unanimously adopted.

The retiring Directors (Messrs. Thorpe, Gray, and Weston) were then re-elected; and Mr. F. Ransom was appointed an Auditor in place of Mr. F. Bennetts, who had retired on account of ill-health, and to whom a vote of thanks was accorded for his services.

The usual complimentary vote of thanks was accorded to the Chairman, and the proceedings closed.

At the Meeting of the Hastings Town Council on the following day—the Mayor (Mr. Stubbs) presiding—the Lighting Committee reported that since the appointment, on the 1st of June last, of Mr. W. C. Young, F.I.C., F.C.S., as Gas Examiner, he had twice tested the gas at the works of the Hastings and St. Leonards Gas Company, and had reported the result as follows:—June 25: Illuminating power, 15·53 candles; sulphur, 11·6 grains per 100 cubic feet; ammonia, 1·4 grains per 100 cubic feet; slight trace of sulphuretted hydrogen. Pressure, at 9 p.m., June 25, 2·8 inches; June 26, at 3·50 p.m., 1·5 inches. Aug. 25 and 27: Illuminating power, 15·41 candles; sulphur, 9·8 grains per 100 cubic feet; ammonia, 0·6 grain per 100 cubic feet; no trace of sulphuretted hydrogen; day pressure, 1·5 inches; night pressure, 3 inches. Mr. Young stated, in regard to his first report, that as the Company's Act requires the gas to be wholly free from sulphuretted hydrogen, they had failed in this respect. He added: "The sulphur, ammonia, and sulphuretted hydrogen tests extend over a period of 20 hours; so that the above results represent the average amount of impurities contained in the gas supplied between about eight p.m. on the 25th, and four p.m. on the 26th of June."

Mr. JENNER, in moving the reception of the report, remarked that he was placed at a slight disadvantage in not having seen that morning's local journal, which gave a report of the Company's meeting on the previous day. He understood the Lighting Committee were dealt with somewhat harshly. He believed one great fault they were charged with was that they did not bring forth the report of the Gas Examiner soon after it was received by the Committee. The reason was simply this: The Committee did not receive the report of the test until after the agenda papers had been returned for the Council meeting. It would have been somewhat out of order if it had been brought forward without having been noticed on the agenda. They certainly had no idea whatever of keeping back the report because it was a good one. He believed the Chairman of the Company had said that if it had been a bad one they would have given it at once. This would not have altered the case at all. But that afternoon they had the advantage of having the reports side by side, together with the requirements of the Gas Act. Now, he was of opinion that both reports were very satisfactory indeed. The Act required the Company to supply gas of 15-candle illuminating power. In the first report they had 15·53 candles. This was very gratifying indeed. The sulphur was considerably below the amount allowed by the Act; it was 11·6 grains, compared with 25 grains per 100 cubic feet. The presence of ammonia, about which, he believed, there was no restriction, was very small. The most objectionable part was the sulphuretted hydrogen. The Act required that it should be quite absent. In the one report there were slight traces of it; but in the second none. The illuminating power of the gas in the second report was not quite so good; but the difference was very slight, and the quality was considerably above the standard required. The sulphur had been reduced from 11·6 to 9·8 grains, and the ammonia to 0·6 grain. He thought this report was a very satisfactory one, and one which would compare most favourably with the gas supply of any town in the kingdom. It was also satisfactory because it showed that the Directors of the Gas Company had acted upon the information contained in the first report. As to the pressure, it was considerably beyond that required by the Act. If the pressure was really acting injuriously upon the gas consumers, it was their own fault, because they could regulate the supply if they chose to do so. He was glad that the returns were as satisfactory as they had turned out to be. He trusted the Company would feel that the thing had worked so admirably that they might be induced to still further reduce the price of gas at no very distant time. He was quite sure their interests would not suffer by such a course.

Mr. REVILL seconded the motion. He said he agreed in the main with what had fallen from the Chairman of the Lighting Committee; but he wished to know whether there was any regulation with regard to the pressure of gas in the mains. He had heard many large consumers say that, although the price was less than formerly, the charge for the quantity consumed did not diminish in any way, and that this was accounted for by the extra pressure put on by the Company. He thought this was a point which should, if possible, be taken in hand by the Committee.

Mr. B. F. MEADOWS read the clause in the Company's Act relating to the pressure—viz., that it should be not less than 6·10ths in the day, and 8·10ths at night.

Mr. REVILL: There is a minimum, and not a maximum.

Mr. JENNER remarked, as to the publication of the reports, that he would endeavour in future to have each one brought up at the Council meeting following the date of its presentation.

The report was adopted.

THE COST OF THE TRANSFER OF THE SHEFFIELD WATER-WORKS TO THE CORPORATION.—The minutes of the Water Committee of the Sheffield Corporation which were presented at the meeting of the Town Council last Wednesday, included a detailed account of the parliamentary costs incurred in promoting the Sheffield Corporation Water Act and opposing the Sheffield Water Bill of last year, and of the costs of the polls of owners and ratepayers on the Corporation Bill. The account shows payments amounting in the aggregate to £12,544, in addition to £1900, the cost of the proceedings under the Borough Funds Act. A sum of £2862 was returned as the cost of witnesses.

STRIKE OF GAS STOKERS AT SALFORD.

The stokers employed at the Regent Road Gas-Works of the Salford Corporation (about 80 in number) have left their employment in consequence of the introduction of changes in the work of the retort-houses by Mr. Shoubridge, the new Engineer and Manager. It appears that under the old arrangement, a stoker's daily task was to charge a certain number of retorts with coal amounting in all to 2 tons 5 cwt., and draw and quench the coke. In addition to this he had to wheel the coke, which amounted to about 27 cwt., to the heap in the yard, to wheel in his coal, and attend to one of the furnaces; so that the weight handled per shift was: Coal loaded up, wheeled into the retort-house, and charged into the retorts, 2 tons 5 cwt.; coke wheeled out, 1 ton 7 cwt.; furnace refuse wheeled out (say), 2 cwt. For this work he received 5s. The new arrangement consisted in subdividing the work into four classes—(1) stokers, who simply charged and drew the retorts, and quenched their coke; (2) coal wheelers; (3) coke wheelers; and (4) firemen, for the furnace work proper. The firemen and stokers, being skilled men, were paid the same rate as before—namely, 5s. per day. The coke wheelers, who handled about 5 tons of coke, received 4s. 3d. per day. The wheeling of the coal was done at a piecework rate per ton. It is considered by the Manager that the new system is really better for the men than the old one, because the stokers and firemen are not obliged to go out of the retort-house during their work, whereas before they were compelled to leave the retorts every few minutes, and wheel their coke into the yard in all states of the weather. Notwithstanding that the quantity of material handled is really less than under the old system, the men assert that it is physically impossible for them to work under the new. One feature of the latter system is that the work is done in six shifts, each lasting about three-quarters of an hour. The stoker then rests for about an hour and a quarter, when he begins another spell in the same way; so that he gets altogether about five hours' work and seven hours' rest in the twelve-hour shift. The men gave the Gas Committee seven days' notice, which expired in some cases at six o'clock on Thursday night, and in others at six o'clock on the following morning. Before the expiration of the notices a proposal was, we understand, made that they should withdraw them, in order to afford time for discussion of the matter in dispute. This they declined to do; and the Committee have therefore been obliged to obtain other men to carry on the work. A large number of applications have been received from stokers in different parts of the country; and the Committee do not anticipate any difficulty in filling the vacant places.

THE BURY CORPORATION GAS-WORKS ACCOUNTS.

The Borough Auditor for Bury (Lancs.) has presented to the Town Council his report for the year ending March 31 last, in the course of which he gives the following tabulated statistics:—

The rental for the past year, including meter-rents, is	£27,696 19 0
Residual products, &c.	8,978 12 2
	£36,675 11 2
The cost of manufacture and distribution and expenditure on buildings and plant charged to revenue amounts to	28,079 3 6
Leaving a gross profit of	£8,596 7 8
From this is deducted—	
Interest on loans and stock	£3,644 16 7
Rebate on stock issued.	100 0 0
Sinking fund	3,140 9 0
And carried to reserve fund, raising it to the maximum of £5000	1,605 11 10
	£4,909 17 5
Leaving a net profit of	£105 10 3

One moiety of which, £52 15s. 2d., is taken to general rate, and the other moiety is added to the previous year's revenue balance. This method of treating the profits (says Mr. Merchant) is in pursuance of a resolution passed by the Council on the 1st of December, 1887. The books and the bills sent to consumers show the amount due for gas at 2s. 11d. per 1000 feet; and a deduction of 4d. per 1000 for share of profits. This 4d. has not, however, been taken out of the profits; therefore the rate should have been stated simply as 2s. 7d. per 1000. This anomaly, he says, is no doubt explained by the resolutions as to the price of gas for the year having been passed before the Council had finally dealt with the year's statement of accounts.

THE GAS QUESTION AT BIRKENSHAW.

Last Thursday, in compliance with a numerously signed requisition of occupiers and property-owners to the Chairman of the Birkenshaw Local Board, a well-attended meeting was held in the Temperance Hall, "for the purpose of considering the gas question, the offers made by the Gomersal Gas Company to supply gas to the consumers in the district, the present excessive prices charged by that Company, and the advisability of adopting other means of lighting the district, either through the aid of another company, or otherwise, as may be determined." The Chairman of the Board (Mr. T. Pitts) presided. Mr. B. Crowther, as Chairman of the Gas Committee, read some correspondence which had passed between the Gomersal Gas Company and the Local Board in their endeavours to get suitable reductions. Special attention had been given to the question by the Local Board; and they, along with some of the largest consumers in the district, had waited upon the Gomersal Company, who had issued a revised scale which was only an advantage to the largest consumers. These terms were considered unsatisfactory. The terms which the Gomersal Company had offered to the Board were then submitted, as follows:—Under 100,000 cubic feet per annum, 11d. discount per 1000, 3s. 3d. net price; 100,000 to 500,000 cubic feet, 1s. 2d. discount, 3s. net; 500,000 to 1,000,000 cubic feet, 1s. 5d. discount, 2s. 9d. net; 1,000,000 to 1,500,000 cubic feet, 1s. 8d. discount, 2s. 6d. net; 1,500,000 cubic feet and upwards, 1s. 11d. discount, 2s. 3d. net. On receipt of the amended terms, the Board and the large consumers referred to decided unanimously that, whilst thanking the Company for the small concessions, they could not accept them as a satisfactory settlement, and advised the Company to effect a further reduction. What the consumers asked for was a reduction of 3d. per 1000 feet on the two scales. The Gomersal Gas Company had replied, stating that, inasmuch as they had made reductions amounting to 1s. 3d. per 1000 cubic feet during the last few months, which they did not consider a slight concession, and having carefully gone through the case, the Directors could not make any further alteration. They quoted a number of gas companies and local boards whose charges were in excess of the Gomersal prices, but had carefully avoided, so the speaker said, quoting either the prices of the Drighlington and other companies whose scales of charges were less than their own. Mr. Crowther advised the meeting to agree, if possible, with the Gomersal Company; and if this could not be done, they ought, he said, to consider the question of providing their own gas-works, though the Board would only act in accordance with the expressed wishes of the meeting. After several consumers had spoken in opposition to the Gomersal prices, it was resolved—"That in the opinion of this meeting the revised

terms of the Gomersal Company cannot be accepted as satisfactory, and that the Local Board be urged to strongly adhere to the resolution adopted by them, and not to light the public lamps in the district until a concession be made." A further resolution was adopted, urging the Local Board to ask Mr. Matthew Hillas, of Tong (who, it may be remembered, receives a supply from the Bradford Corporation), if he would be prepared to serve Birkenshaw as well as Tong Street. It was stated that several of the consumers, including members of the Local Board, had discontinued to use gas; and these expressed their determination to adhere to this practice. Thanks were given to the Chairman and the various speakers, and the meeting closed.

THE WOLVERHAMPTON CORPORATION AND THE GAS COMPANY.

THE SPECIAL COMMITTEE'S REPORT.

At the Meeting of the Wolverhampton Town Council on Monday last week—the Mayor (Alderman J. Jones) presiding—the report of the Special Sub-Committee appointed "to consider the question of the supply of artificial light for the use of the inhabitants of the borough, and to obtain such professional advice with reference thereto as they might think fit," was presented. The report was given in the JOURNAL last week.

Mr. IRONMONGER, the Chairman of the Committee, moved—"That the report of the Special Gas Committee, this day presented to the Council, be adopted; and that, in accordance with the recommendations therein contained, a deputation, consisting of the Streets Committee and the Chairman of the Special Gas Committee, be and they are hereby empowered to meet the Directors of the Gas Company, with a view of obtaining the concessions embodied in the report, or such other terms as they may consider satisfactory, relative to all or any of the matters dealt with in the report, and to cause the corporate seal to be affixed to any agreement which may be necessary to give effect to any negotiations between the Committee (as representing the Council) and the Gas Company, and that, in case satisfactory terms cannot be arranged with the Gas Company, the whole question be referred to the General Purposes Committee to take such action thereon as they shall think fit." He said that he did not propose to trouble the Council with very many remarks concerning the report, as it was of sufficient length itself. It dealt with the question fully, and gave the views of certain experts who had been consulted, together with the criticism of the Gas Company. Since the publication of the report, he had received further information, which he would lay before the Council, and which was confirmatory of what was stated in the report. After referring to the paragraphs in the report which dealt with the mode of lighting by electricity, he remarked that the Committee had obtained very valuable information from 87 towns. He had before him certain bills and charges issued by various corporations and companies. From them he found that at Nottingham the price of gas per 1000 cubic feet was from 2s. 2d. to 2s. 4d.; whilst the price at Wolverhampton was 2s. 6d. with 16²⁵-candle light. There were four points to which he wished to call their attention—namely, the price of gas, the illuminating power, meter-rent, and discount for cash payment. The consumers in Wolverhampton did not obtain discounts, and had to pay meter-rent. At Nottingham the quality of gas supplied was equal to 18¹/₂ candles; but there was no discount given, and meter-rent was charged. At Bradford the price was 2s. 3d. per 1000 cubic feet; the candle power 18¹/₂; and discount was allowed according to the quantity of gas supplied—the discount varying from 2¹/₂ to 12¹/₂ per cent. At South Shields the price was 2s. 3d. per 1000 cubic feet, with a discount of from 7¹/₂ to 20 per cent. At Wigan it was 3s. 1d., subject to a discount of 4s. in the pound; and the illuminating power of the gas was equal to 19¹/₂ candles. At Leeds the price was 1s. 10d.; illuminating power 19-10 candles; and the discount 5 per cent. for cash in a month, or 2¹/₂ per cent. in two months. The charge at Leicester was 2s. 4d. net; and the illuminating power, 18 candles. At Walsall, 2s. 5d. net; and the illuminating power was 16¹/₂ candles. At Tipton the price was 2s. 5d.; illuminating power, 17¹/₂ candles; and the discount, 5 per cent. At West Bromwich 2s. 5d. was charged; with an illuminating power of 16¹/₂ candles; and 5 per cent. discount. Birmingham charged 2s. 3d.; the illuminating power was 17¹/₂ candles; and the discount was 5 per cent. At the four last-named places—viz., Walsall, Tipton, West Bromwich, and Birmingham, there was no charge for meters. He thought when they looked at the question of meter-rent, it was one which should be very seriously considered. The meter was for the protection of the Gas Company; therefore, he thought, they should not ask the gas consumers to pay for that protection. The returns he had given were in favour of Wolverhampton; but in some cases they were less favourable as regards quality and price. There was nothing in the situation or circumstances to prevent Wolverhampton doing as well as other boroughs. There was another item worthy of consideration, and that was the payment by the Gas Company of 10 per cent. dividends free of income-tax. This was a matter which was gone into in 1866 when the concern and business of the gas undertaking was inquired into at the Quarter Sessions. From 1852 to 1866 the Company paid on behalf of the shareholders no less than £3610 16s. 9d. in income-tax. The amount paid by the Company upon the last half year out of their profits represented two-thirds of a penny per 1000 cubic feet; and this would have done something towards a penny reduction in the present price of gas. They were told that £2672 had recently been taken from the reserve fund to make up the deficiency on profits, which sum would represent 1'83d. per 1000 feet, almost equal to a reduction of 2d. This was of sufficient importance to call for the attention of the Corporation, especially when they were assured by the Town Clerk that, in his opinion—having regard to the decision in a case which had been brought before the Quarter Sessions—it was illegal. Upon that he (Mr. Ironmonger) was prepared to stand. Then there was another matter which was of great importance, and that was with regard to the working of the Company. He contended they had a right as consumers, and especially the Corporation, as protectors of the public, to see that the Company did not abuse the privileges given to them by Act of Parliament. Certain privileges had no doubt been put into the hands of the Company; and evidently it was the intention of the Legislature in limiting the dividend that the utmost care should be exercised in the manufacture and distribution of gas, so that, when they had earned their 10 or 6 per cent. as the case may be, they should devote the additional profit to the benefit of the consumers. The Accountants engaged by the Committee, who had had a long experience, had made some very strong remarks about the matter. With regard to the cost of coal and the yield of gas, the Wolverhampton Gas Company did not compare favourably with the other boroughs and companies which were called in review. The average cost of coal per 1000 cubic feet of gas for eight corporations quoted was 12-57d., and 13-80d. for ten private companies; whereas the Wolverhampton Gas Company reached 17-60d. By the latter Company coal was used for fuel instead of coke; and the revenue from coke was a material element in the calculation. Taking the same eight corporations, the average cost of coal, less residuals, averaged 7-31d.; the ten companies, 7-62d.; whereas the Wolverhampton Company ran up to 12-26d. When they had looked at the accounts of their neighbours for 1887, they found that Walsall stood at 7d. and

Birmingham at 5.59d.; so the comparison made between Wolverhampton and Birmingham in the reports for 1886 was borne out by the same comparison in 1887. In regard to the gas sold, Wolverhampton stood better in 1887 than in 1886; but even now was still a very large percentage behind the figures representing other towns, both local and distant. From the Board of Trade returns for 1885, Wolverhampton looked peculiar, compared with the filed accounts presented to the Clerk of the Peace. The latter showed the amount of coal carbonized to have been 51,600 tons; whilst the former showed the quantity to have been 41,220 tons, or a difference of 10,380 tons. It seemed strange that the Gas Company should have sent out figures showing such a large discrepancy. Then there was a great difference in the figures relating to the amount of gas sold. According to the Wolverhampton filed accounts, the quantity was 338,826,000 cubic feet in 1885; and from the Board of Trade returns it was 349,000,000 cubic feet—showing an excess of 10 million cubic feet. He did not bring these forward as accusations—they might be mistakes; and he only mentioned them as being a passing discrepancy worthy of notice. The question of fittings was a mystery. He took it that the rental of the meters had nothing to do with the fittings; and the explanation of the Gas Company was unsatisfactory in this respect. The general conclusions of the Committee fully expressed all their wishes; but there was one point with respect to illuminating power which demonstrated the ingenuity of the Company when they had to deal with a Committee who had not fully gone into the matter. The Company had said that if in Wolverhampton the gas was tested at the works, as they stated it was in Birmingham, the results would be equally favourable to those of Birmingham. This statement satisfied the Streets Committee; but the fact was that the Birmingham gas was tested in different parts of the borough, and the statement of the Company therefore fell to the ground. The Company had simply ignored and snapped their fingers at the Corporation; and probably were at that moment perfectly calm and at ease about this matter, thinking that the Corporation had been giving themselves unnecessary trouble. He hoped the recommendation of the Committee would be adopted, and that the Company would accept the suggestion that the time had arrived when, in common with all other commercial undertakings, they should recognize the demands of the times and act accordingly. He thought that 2s. per 1000 feet, with 5 per cent. discount, and no charge for the meters, would be a fair price; and there was a feeling that the Company might do this, and still maintain their dividend and put something to their reserve fund. The Committee had done their duty in inquiring into the matter; and he trusted the Company, in their own interest and that of the public, would accept the expression of public opinion as now marked by the Council. It was the duty of the Corporation to make arrangements for periodically testing the gas in different parts of the borough. They had a very large claim irrespective of all other consumers. They paid no less than £1000 a year, and ought to be served at a considerable reduction in the price of gas. This was their personal business; but they had a much larger scope, and that was the protection of the inhabitants of the borough.

Mr. MARSTON seconded the motion.

Mr. SAUNDERS thought the Council were very much indebted to the Committee for their report, which he should support. But he considered the question arose whether the Corporation could not entertain the idea of lighting independently of the Gas Company. He was of opinion that the Company should pay their own income-tax.

Alderman GIBBONS said the Committee deserved great credit for having prepared the report; but they seemed to have gone into a lot of details almost unnecessarily. They would never be able to influence the Gas Company until they could compete against them. He thought the Committee ought to have paid more attention to the electric light. He would not dream of lighting 60 miles of streets by electricity; but he thought

that the centre of the town might be so lighted. He was sure tradesmen would take to it, if it would compete against the gas; and it would add greatly to the attraction of the town.

Mr. WILLIAMS did not think the Committee's report would at all influence the Gas Company. He had heard the question argued out before by the Streets Committee, who had done all they could to secure a reduction; but the reply of the Company to their arguments was that if they reduced their charge to the Corporation, they would have to increase it to the ratepayers to make up for it. He did not think the Committee had followed out their instructions. Those instructions were that they should inquire into the artificial modes of lighting the borough. The question of the electric light had not, in his opinion, been fairly dealt with. The Chairman of the Committee had said he could give the amount which it would cost to put down an installation of the electric light. Why did he not do so? The first paragraph of the report was about oil-lamps. In 1789 that would have been a proper matter for consideration—(laughter)—but he did not think they ought to go back to such things as that now. He did not consider the report worth the paper it was printed on. The Company would never take any notice unless some alternative scheme were brought forward.

Mr. COUSINS thought the report of the Committee must commend itself generally to the Council. If the Company were not prepared to deal with the Committee in a reasonable manner, then would be the time for them to adopt a plan such as that foreshadowed by Mr. Williams.

Alderman WRIGHT considered the Committee had not dealt with the matters they were appointed to deal with. They had done a good deal to prove an indictment against the Gas Company, which came to comparatively little. His view of the matter was that if the Corporation were to deal with the Gas Company, it must be on the lines suggested by Alderman Gibbons. They must find something the price of which was below gas at 2s. per 1000 cubic feet. He believed that the electric light was at present so hampered by patents that they would not be able to sufficiently popularize or cheapen it to make it compete with gas. If they could induce the Gas Company to reduce the price of gas, he should not grumble; but he was afraid that they had no more chance of doing so than they had previously. The allowance of discount was a very fair thing; but whether or not they would get it was another matter. If the Company did not charge meter-rent, the money would be put on in another way. He did not care so much for a reduction of the price of gas, as 2s. 6d. per 1000 cubic feet was not such a ruinous price; but he would like to have the gas purer. He was afraid that nothing would come out of the report of the Committee.

Alderman DICKINSON thought the report might be very useful in that it contained a good deal of information as to the working of gas companies. If what Mr. Ironmonger had said was true, it seemed a reflection upon the management of the Wolverhampton Gas Company; and the Company would have to meet these matters publicly, and in a straightforward manner. They would not be content to go on paying 10 per cent. if the business was badly managed. It was absolutely necessary that the Company should be managed as efficiently and as economically as possible. If the concessions asked for were granted, he thought there ought to be representatives of the Council in the Gas Company to look after the interests of the Council. The Company already recognized the principle in so far as to send in a report. He was of opinion that it was unfair that the public should pay income-tax in connection with the Company.

Mr. TATE considered that the thanks of the town were due to the Committee for the report they had presented. He believed the introduction of electric lighting would bring the Gas Company to a better sense of their situation.

The resolution was then amended to read, "subject to the approval of the Council," and was carried unanimously.

BEAUTIFUL TAR.

SONG OF AN ENTHUSIASTIC SCIENTIST.

Air—"Beautiful Star."
[From Punch.]

Beautiful Tar, the outcome bright
Of the black coal and the yellow gas light,
Of modern products most wondrous far,
Tar of the gas-works, beautiful Tar!
Tar of the gas-works, &c.

In fancy's ear thou seem'st to say,
"Follow me close, I am bound to pay.
On me experimenters freely try;
For if there's a *multum in parvo*, 'tis I."
Tar of the gas-works, &c.

Men told us once, with a cheek quite calm,
Of the things that the Arabs could get from the palm;
But that fraud botanic is distanced far
By the modern marvel, the black Coal Tar.
Tar of the gas-works, &c.

House and garments, victuals and drink,
The nomad got from the palm, I think;
But as source of beauty, and bliss, and balm,
Coal tar from the palm-tree must bear the palm.
Tar of the gas-works, &c.

Protoplasm? Oh, that's played out;
The true protoplasm is Tar, do doubt.
As "promise and potency," Tar must take
What vulgar sciolists call "the cake."
Tar of the gas-works, &c.

There's hardly a thing that a man may name
Of use or beauty in life's small game,
But you can extract in alembic or jar
From the "physical basis" of black Coal Tar.
Tar of the gas-works, &c.

Oil and ointment, and wax and wine,
And the lovely colours called aniline;
You can make anything, from a salve to a star,
If you only know how to, from black Coal Tar.
Tar of the gas-works, &c.

'Tis found the basis of all things sweet;
Sugar is settled, and beet is beat;
The Western root and the Eastern cane
With ubiquitous Coal Tar contend in vain.
Tar of the gas-works, &c.

You can carry the stuff in your pocket or hat,
And it will not hurt you, or make you fat;
Of saccharine matters the wholesomest far
Is the stuff extracted from black Coal Tar,
Tar of the gas-works, &c.

The very bees mistake it for honey!
'Tis a fount of pleasure, a mine of money;
And the Bounty question without a jar
Will soon be settled by black Coal Tar,
Tar of the gas-works, &c.

Triumph, O Tar! Stuff half divine!
The world's whole interests soon will twine
Around thine essence the subtlest far,
Tar of the gas-works, black Coal Tar—
Tar of the gas-works, black Coal Tar!

AUSTRALIAN GASLIGHT COMPANY.—The report of the Directors of this Company for the six months ending June 30 last stated that the net profits, with the balance brought forward, amounted to £49,450, out of which a dividend at the rate of 7½ per cent. was recommended. This would absorb £46,453; leaving a balance of £2987 to be carried forward. The Engineer (Mr. T. J. Bush) reported the plant to be in good order; and the erection of the new retort house and holder at Mortlake was proceeding to his satisfaction.

PUBLIC LIGHTING DISPUTE AT BEWDLEY.—The week ending on the 8th inst. was one of almost complete darkness in the streets of Bewdley during the night time, for, owing to the dispute which has existed between the Corporation and the Directors of the Gas Company in regard to the charge to be made for lighting the public lamps, there was no illumination of the streets, with two exceptions (one near the Town Hall), which, however, served to make the surrounding darkness more painfully evident and keenly felt. The difference between the two bodies was one of 3s. per lamp; and the Corporation expressed their determination either to enforce their own terms or resort to oil-lamps. A *modus vivendi* has, however, been arrived at; and on the evening of the 8th inst. all the lamps were lighted, much to the satisfaction of the residents and the safety of the borough. The Directors of the Gas Company had not increased their charge; but the Corporation felt that the time had come when some concession should be made. The price previously paid was £4 3s. for a season of eight months; the lamps not being lighted on two nights before, and for an equal period after the full moon. This was at least equivalent to a charge of £4 4s. for the year, which was looked upon as much above the average charge made in other towns.

THE BOLTON GAS COMMITTEE AND THEIR STOKERS.—As already intimated in the JOURNAL, the Gas Committee of the Bolton Corporation have come to an arrangement with the stokers on the question of the terms of their employment and the mode of carrying out the work. It was reported to the Council last Wednesday, that the Committee had resolved that the Engineer should be allowed to arrange for the employment of some of the stokers on eight hours' service, and others on twelve hours' service, at his discretion; and that this arrangement had been agreed to by the stokers.

THE OIL LIGHTING AT ERITH.—At the meeting of the Erith Local Board on Monday evening last week, among other accounts ordered to be paid was one of £188 6s. 11d. to the Defries Public Lighting Company, on account of oil-lamps, &c. It was stated that some of the lamps were not lighted on several nights; and a conversation arose with reference to the correspondence which had taken place between the Clerk and the Defries Company on this matter. In the contract which had been signed by the Company, it was stated that a penalty of 2s. 6d. per night shall be imposed for each lamp that was not lighted; and the Company objected to this penalty being enforced, as they said the lamps had been wilfully put out, after being lighted, by some evil-disposed person. The Chairman said an inspection had been made by order of the Board, by persons specially appointed, between eight and eleven o'clock on two nights, and on each of these nights five or six lamps were not lighted. The lamp at the Public Hall was not alight four nights in succession; and as the light there could not be got at except by using a ladder, it could not be tampered with in the way suggested by Messrs. Defries. The question of dealing with the Company in this matter was deferred for decision in Committee.

THE TOWN OF COWPEN IN DARKNESS.

AN EXTRAORDINARY DEMONSTRATION.

Last Tuesday night there was witnessed in the Northumbrian town of Cowpen one of the most extraordinary demonstrations which have ever taken place in that part of the country. It was a public protest, on the part of the inhabitants, against the conduct of the Local Board in throwing the town into darkness, in consequence of a dispute they have been engaged in with the Gas Company as to the terms on which the latter are to light the public lamps. It is unnecessary to enter into particulars of the quarrel; suffice it to say that the result is that there is no public light of any kind in the township, and therefore, in the language of a local paper, "pedestrians of the night run the chance of breaking their necks at every whistitch." As a matter of fact, the daughter of a working man in the town had her foot seriously injured owing to the darkness of the streets; and it was owing to a suggestion of her father that a public demonstration was made. The idea was taken up by two or three of the tradesmen, and the affair organized by them. It is easily understood that business men, with shops on the principal thoroughfares should feel indignant at the action of the Board, which is daily depriving them of a large section of their previous patronage. On Friday and Saturday nights this is especially found to be the case; and miners will not come into, and spend their money in a town in a state of the most absolute darkness. A copious stream of ready cash is thus diverted in other directions every week-end. It has been stated by one tradesman that the town suffered a loss of £500 in a fortnight owing to the decreased expenditure caused by the non-lighting of the streets. The first indication of what was going on was the appearance in almost every shopkeeper's window, on the night preceding the demonstration, of a long yellow bill, couched in amusing phraseology, inviting the inhabitants to take part in a "grand installation ceremony of the new light," to take place on the next night; the procession to start from the Market Place at 8.30. The order of the procession was set out at great length. The first contingent was to consist of four showman's naphtha lamps; the second, of a metal band of juvenile artists; the third, stable lanterns; the fourth, ships' port and starboard lights; the fifth, railway signal and danger lamps; the sixth, Davy lamps and "Betties;" the seventh, household lanterns; the eighth, 50 superfine dips; the ninth, turnip lanterns. In a note appended to the order of procession it was stated that "a stopping halt" would sometimes be made, when search parties would be sent out to "try and discover the missing brains of the Cowping Lokil Broad." It was further set forth as follows:—"The procession will proceed by way of the principal streets in Waterloo and Cowpen Quay, returning to the Market Place, where a resolution highly eulogistic of the enlightened policy of the Will-o'-the-Wisps who boss Cowping, and of the electrical conduct of some of the fellows, will be submitted for the enthusiastic and loyal acceptance of the assembled millions. Every man-jack who has the unspeakable satisfaction of possessing a lantern of any sort is requested to bring it properly trimmed, but not lighted, to the Hedley Fountain at 8.15. Don't forget to bring a match; or if you can afford it, two. Be desperate and fetch T-W-O matches. The signal to light up will be given at 8.30 punctually, and will consist of one loud, dead-awakening howl from the splendid metal band. Trim your lamps and be ready!" The local paper from which the foregoing particulars have been taken states that although many who perused the bill were not inclined to take seriously what it set forth, a sufficient amount of curiosity was aroused to induce some thousands of spectators to assemble on the following evening in the Market Place, which by half-past seven was inconveniently crowded. The spectators, growing impatient, amused themselves by taking up the names of certain members of the Board, and howling at them; so that it was deemed advisable to commence proceedings. Just before eight o'clock, from 70 to 100 miners went down to a private house in the town, where about 300 torches had been stacked, and each man brought away two or three with him. As the town clock struck the hour, the men in the van of the procession lighted up; those behind quickly imitating them. In less than five minutes, we are told, the street was "one tremendous blaze of light, and a seething, struggling mob, consisting of thousands of people, was discovered following on behind the torch-bearers." Fortunately, the crowd was orderly and good-humoured; and having perambulated the town, the procession dispersed, without any breach of the peace being committed, or any mischief done. A good deal of horse-play was, of course, indulged in; and this was to be expected. Altogether, however, there is no doubt that the demonstration was a sound and emphatic protest by the tradesmen of the town against the action of the Local Board; the Directors of the Gas Company having had nothing whatever to do with it. It should be mentioned that the Local Board have been entertaining a project for lighting the town by means of electricity; and a futile attempt was made by a few members who have identified themselves with the scheme to get up a counter-demonstration. A placard besring the inscription, "The Electric Lighting Brigade—Death to King Bunkum and Tin-ribs," was borne along by a lad, followed in an aimless manner by about a dozen children. This noble army endeavoured, as far as their feeble lungs would allow them, to send up a cheer. But they had to give way before the stronger forces, and were seen later on with tattered banner, torn pinafores, and besmeared faces. As to this electric lighting project, it seems that the negotiations have come to a complete deadlock. The Electric Company require the Board to enter into a seven years' lighting contract; to guarantee the annual payment to the Company of a sum of £920, or thereabouts; a local Company to be formed to take over the contract, &c. on the lines of Barnet; the local Company to be allowed seven years for the purchase, at £920 a year, of the plant, &c., with which the Electric Company will equip the concern; and on the payment of this £6000 odd the Electric Company will finally hand over the concern to the local Company. The Board cannot say that they have the support of the local press in this matter; for the last issue of the *Blyth Examiner* contains a couple of columns of matter specially bearing on the Barnet experiment, in which this unfortunate undertaking is held up as a caution to the Cowpen authority. The article concludes as follows:—"We do not know that we shall now trouble ourselves much further about the craze of the Cowpen Board upon this subject. We have done a good deal to enlighten the mental darkness of the members, and have by no means exhausted ourselves of all we could say, and of all that it seems desirable the members of the Board should know—for they evidently know precious little of what they so lightly have taken in hand. But we must now leave them mainly in the hands of their indignant constituents. They are not sustained by public opinion in their course of action; and if members have personal animosity against the Gas Company, it is the most unwarrantable thing in the world that they should use the official position in which the ratepayers have placed them, to carry out, a scheme that has no better element in it than private revenge." It is believed that another and larger demonstration will take place next Thursday night, when something like 500 torches will be employed. It will remain to be seen what steps the Local Board will take in face of this forcible expression of public opinion on their proceedings. In closing our notice of this extraordinary affair, it may be well to mention again that these demonstrations

are not got up in favour of gas, but simply as a protest against the darkness in which the Local Board have chosen to involve the district. The leaders of the movement declare that, so far as they are concerned, it is immaterial whether the place is lighted by electricity, gas, oil, or even farthing candles; but they are determined that it shall be lighted, and they intend to "demonstrate" until it is. Let the Board, then, at once return to gas, satisfy their constituents, and put an end to all this turmoil.

METROPOLIS WATER SUPPLY.

According to the returns furnished to the Registrar-General by the London Water Companies, the average quantity of water supplied daily to the Metropolis in the past month was 172,869,385 gallons, as against 177,602,556 gallons in the corresponding month of 1887. The number of houses served last month was 741,399, or 233 gallons per house, and 29.9 gallons per head of the population. In August, 1887, the number of houses supplied was 728,469; and the quantity of water allowed for each person 31.3 gallons. Of the entire bulk of water supplied last month, 85,944,463 gallons were drawn from the Thames, and 86,924,922 gallons from the Lea and other sources.

Dr. E. Frankland, in the course of his report to the Registrar-General on the quality of the Metropolitan water supply last month, makes the following remarks:—"The average proportion of organic matter in the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies, which had in the previous month exhibited an increase, suffered in August an almost equally marked diminution; the latter being most conspicuous in the samples of the West Middlesex and Grand Junction Companies' supplies. All the samples were clear and bright. The water principally derived from the Lea, and distributed by the New River and East London Companies, contained less organic matter than any of the Thames supplies. Both samples were clear and bright. The deep-well waters of the Kent and Colne Valley Companies and of the Tottenham Local Board of Health contained, as usual, only a very small proportion of organic matter; and the Colne Valley Company by softening their supply with lime thereby rendered it also of excellent quality for washing and all other domestic purposes. The sample of the Colne Valley Company's supply was very slightly turbid, apparently due to the presence of a trace of carbonate of lime in suspension."

EAST LONDON WATER-WORKS COMPANY.

HALF-YEARLY REPORT OF THE DIRECTORS.

The report of the Directors of this Company to be presented to the proprietors, together with the accounts, at the half-yearly general assembly on the 2nd prox., is as follows:—

The accounts for the half year ending the 24th of June last are here, with submitted. The comparative revenue and expenditure are—

1888—Revenue from all sources for half year ending			
Midsummer	do.	do.	£123,927 8 0
1887—Do.	do.	do.	124,554 3 6
		Increase	£2,373 4 6
1887—Expenditure for half year ending Midsummer—			
Maintenance			£41,298 9 4
Management			9,686 12 5
			£50,980 1 9
1888—Expenditure for half year ending Midsummer—			
Maintenance			£39,892 5 0
Management			8,832 0 3
			48,724 5 3
		Decrease	£2,355 16 6

The Directors deem this increase of revenue as being moderately satisfactory, having regard to the deplorable condition of some branches of industry in the Company's district. The decrease of expenditure is exceptional, and arises from certain work carried out by the Company appearing to the credit of "Maintenance."

The expenditure on capital account (£17,558) arises from the continuation of the works in hand, and which are now in a forward condition. The new triple-expansion engines at Waltham Abbey have been tested, and found to work satisfactory; and the well and the tunnels in the chalk will, it is hoped, be completed during the present month. The sinking of the large wells at Walthamstow and Lea Bridge is being pushed forward as rapidly as the difficult nature of the work will admit.

The quantity of water pumped was 7,182,563,971 gallons, as against 6,952,914,841 gallons in the corresponding period of last year. The new services laid on numbered 1945, as against 1938 in 1887. The total number now in supply is 161,732. The whole of the water delivered by the Company has been certified as pure and well filtered.

A further sum of £53,000 of debenture stock will be issued by tender in December next, under the terms of the Company's Act.

The Directors regret to announce the resignation of their old friend and colleague, Mr. Thomas Mashiter, who held a seat at the Board for 39 years, but whose failing sight prevents him continuing to exercise the active part he has always taken in the administration of the Company's affairs. The vacancy thus created will be filled up at the meeting.

It is recommended that a dividend upon the ordinary stock of 3½ per cent. for the half year (less income-tax) be declared, payable on the 9th of October. This will absorb £60,219 6s. 9d.; leaving an unappropriated balance of £11,087 3s. 1d.

COMMENCEMENT OF A MAIN-DRAINAGE SCHEME FOR BELFAST.—Last Wednesday the ceremony of cutting the first sod of the new main-drainage works which are about to be constructed for Belfast was performed by Mr. W. McCammond, J.P., the Chairman of the Town Improvement Committee of the Corporation, in the presence of a large assemblage of persons. The section of the work now commenced will cost about £35,000; the entire undertaking, of which the Borough Surveyor (Mr. J. C. Bretland) is the Engineer, being expected to entail an outlay of £300,000.

STAFFORDSHIRE POTTERIES WATER-WORKS COMPANY.—Last Friday week a special meeting of this Company was held at Hanley, for the purpose of authorizing the raising of additional capital by the issue of new ordinary stock. The Chairman (Mr. J. Bull) briefly explained the purpose for which the meeting had been convened. The Directors, he said, proposed to offer £30,000 by the issue of ordinary stock, which amount, it was estimated, would be sufficient to meet their requirements up to next June or the end of the year. Out of the general account it was estimated that parliamentary and other expenses would reach £15,000; and in addition to this the extensions at Hatton would amount to about £10,000. So that the sum proposed to be raised would fully provide for what was required. He proposed—"That the Company be authorized to raise the sum of £30,000 by the issue of new ordinary stock, to be offered by public auction in pursuance of the Staffordshire Potteries Water-Works Act, 1883." In reply to a shareholder, the Chairman said the new stock would rank precisely the same as the old stock for dividend up to 7 per cent., which would be the maximum. The motion was carried unanimously.

LONDON WATER COMPANIES' DIVIDENDS.

The closer anyone looks into the financial constitution of the Metropolitan Water Companies, the more convinced will he be, says the *Financial News*, of the inconvenience arising from their lack of uniformity in regard to capitalization and the distribution of dividends. Nowadays, it is true, Parliament keeps a watchful eye upon the provisions of the Special Acts which are from time to time obtained by the Companies; but no amount of modern vigilance can remove the effects of the laxity which prevailed in bygone years.

The West Middlesex Company can boast of an Act passed in 1806, when it was provided, on the incorporation of the Company, that the subscribers should "be entitled to, and receive the entire and net distribution of an equal proportionate part" of the profits, according to the amounts of their several contributions. This method of distribution was continued when, in 1810, and again in 1813, enlarged powers were conferred upon the Company. Even in 1852, when the most important of this Company's Special Acts was obtained, no express provision was made as to dividends. The capital was then fixed at £506,800, divided into 8300 shares of £61 each. Eight years later, power was taken to raise further capital to the extent of £180,000, either on mortgage or by the issue of new shares, preferential or otherwise. At the same time it was enacted that if in any year the profits were not sufficient to pay the full preferential dividend for such year, the deficiency should not be made good out of the profits of a subsequent year, nor out of any other funds of the Company. Capital issued under a subsequent Act, that of 1869, stands upon a different footing. The sum of £300,000 then authorized, might be issued either as ordinary or preferential, and, as regards debenture stock, the Act provided that the Company might attach "such fixed and perpetual dividend as they think fit."

Of course, the involved provisions which are to be found in some of these Special Acts are to be attributed to the peculiar notions and the grammatical idiosyncrasies of dead-and-gone Parliamentary Agents. Lucidity and uniformity were not the objects which these gentlemen seem to have had in view. The terms of the Special Acts obtained by the Grand Junction Company appear to us to compare favourably with some of those to which we have drawn attention. This Company's Act of 1855 enacts in plain phraseology, that the prescribed rate of profit shall be as follows:—"As regards the sum of £546,000, £10 in the £100 by the year; and as regards the residue of the capital, £7 10s. in the £100 by the year." This is language which whosoever reads can understand; and references to the general law at once become superfluous. The Special Act of 1868, which brought the capital of the Grand Junction Company up to £1,000,000, is no less successful in telling proprietors what their rights are in regard to dividend; and the same may be said of the Act obtained in 1878. It was then necessary to introduce certain qualifications; and it was, therefore, provided that if in any year the net revenue applicable to dividends should be insufficient to pay the full rates previously prescribed, the revenue should be applied in the first place in payment of dividend on all the ordinary paid-up capital up to 7 per cent.; next in payment of a further dividend up to 10s. per cent. on the ordinary paid-up capital created under the earlier Acts; and the balance in payment of dividend upon ordinary paid-up capital entitled to a higher rate than 7½ per cent.

The Lambeth Company's Acts also are not difficult to understand; and we observe that power was conferred upon the Directors to declare interim dividends, so long as they shall not reduce in any way the Company's capital. The Special Act of 1871 has no direct bearing on the adjustment of capital or the distribution of profits.

It now only remains to refer to the financial foundations of the Chelsea Company. The capital and stock of this undertaking are mainly regulated by the Special Act of 1852—that is to say, the general provisions of the Water-Works Clauses Act of 1847 were then incorporated. In 1864, when further powers were acquired, no express reference was made to the General Act as affecting the new capital then to be created. But in 1875 it seems to have been thought expedient to frame the Special Act differently; and, accordingly, we find that the provision of the General Act of 1847, with respect to the amount of profit to be received by the proprietors, was then incorporated. Thus, it will be seen that, in regard to the Chelsea Company, the general law as to the prescribed rate of dividend has been adopted in the Acts of 1852 and 1875; and in the Acts which do not in terms incorporate the general law, there are no express regulations as to dividends. It seems to follow, therefore, that the distribution of profits is regulated entirely by the provisions of the Water-Works Clauses Act of 1847.

THE ASHFORD (KENT) GAS COMPANY AND THE LOCAL BOARD.—There is some suggestion of the purchase by the Local Board of the works of the Ashford (Kent) Gas Company, whose annual meeting was recently held, when a dividend of 7½ per cent. was declared, and a considerable amount of the available profit applied towards the reduction of the debenture debt.

MR. SAMUEL HAYWARD AND THE SALFORD CORPORATION.—Mr. Hayward has called our attention to a letter addressed to one of the local papers in reference to the recent proceedings in the Salford Town Council regarding the costs in the action brought by him against the Town Council. In the course of the letter, he says: "The statement that the action brought against the Salford Corporation by Samuel Hayward 'was dismissed' is not correct. The action was commenced by me in August last year, and continued up to May last. It was only in the early part of that month that I learned the main defence of the action was that the agreement to engage my services to assist the Investigation Committee was not under the Corporation Seal. It was a quibble simply. On learning this I wrote to the then Town Clerk, pointing out to him that the main charges in my account received his approval before being rendered; and it was hardly decent for him to set up such a defence."

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON.—At the close of the meeting of the Leamington Town Council on Monday evening last week, an animated discussion took place in Committee on the vexed question of the electric lighting of the town, for which, it will be remembered, Messrs. Chamberlain and Hookham, of Birmingham, are the contractors. After the letter of Messrs. Shippey Bros., to which reference is made in our "Electric Lighting Memoranda" to-day, had been discussed, Alderman Gilbert moved a resolution to the effect that Messrs. Chamberlain and Hookham be requested to meet the Council in 14 days from that date, to explain fully what course they intend to take to improve what is now considered to be the insufficient lighting of the main thoroughfare of the borough. It is said that this resolution was not seconded until after considerable discussion; and then Dr. Thursfield moved an amendment that an expert be called in to determine the quality of the light now being supplied, and whether it is of the illuminating power specified in the contract. A second amendment was moved to the effect that an estimate be invited from Messrs. Chamberlain and Hookham for the erection of eight arc lamps to be fixed on the Parade as an experiment. This was carried after two hours' discussion.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

This has been the week of valuation courts and the fixing of assessments. Of the former only three cases have come before the public in my district; and of the latter, so far as I can gather, except in special circumstances, the tendency appears to be to lighten taxation—one of the elements enabling this to be done being the reduced charge for public lighting. The appeal by the Stirling Gas Company against the raising of the valuation of their works and plant from £1300 to £1600, without there being any change of circumstances, is the most important of the valuation cases. The Magistrates fixed the valuation at £1500; and notice of appeal was given. There is frequently a disposition on the part of Magistrates, sitting as a valuation court, to try and humour both the assessor and the appellant by fixing a sum midway between the disputed points; and this appears to have been done in the present case. The weakness of the decision seems to be that tenants' profits, over which there has in other cases been so much discussion, have been left out of account. The Assessor allowed deductions for maintenance and interest on capital; and then took the balance of gross profits as the sum at which a tenant would rent them. The Magistrates allowed £100 more than the Assessor. But even that would be an inadequate return to a tenant; and therefore, if the case is taken to a Superior Court, there should be no difficulty on the part of the Company in making good their contention. Another case, that of Strathmiglio, in Fifeshire, was heard at Cupar on Tuesday. It was a small affair; the Company asking that their works should be valued at £55 instead of £72. The ground of the appeal was declining business; the actual profit for the past year having been only £40. This year, it was stated, if there should be any profit, it has been agreed not to divide it. The Court reduced the valuation to £60. At Burntisland, owing to the opening of other docks in the Firth of Forth, there is a declining business at the port. The Valuation Court accordingly reduced the valuation of the harbor; but, on what grounds it is difficult to say, they advanced the valuation of the gas-works and plant from £420 to £626 10s.—an increase of £206 10s. The works have not been improved during the year. This looks as though the authorities were attempting to make up for their loss of revenue from the harbor by laying it on to the gas-works. If this be their object, it is, in one aspect, a tribute to the vitality of the gas industry that it should be selected to bear the extra burden; but, on the other hand, it is another instance, already too common, of crippling the gas supply in the interest of other public objects.

Another question, akin to the valuations of gas-works, which cropped up at the Stirlingshire Valuation Court is the valuation of electric lighting plant. The proprietor of Blair Lodge School has this season greatly enlarged his premises, at a cost of more than £7000, of which sum £1400 is set down as the cost of introducing electric lighting into the institution. In respect of the improvements, the Assessor proposed to raise the valuation from £285 to £360. Even such an enlightened man as Sheriff Scott-Moncrieff thought the electric lighting should not be assessed, because (wonderful reason!) it was a luxury, and was not a source of profit. The Assessor pointed out that it saved the price of gas. With this explanation, the Sheriff became quiescent; and the cost of introducing electric light must be held to be included in the lump sum of £320, which the Court fixed as the valuation.

The Perth Gas Commission, at their meeting on Monday, instructed their Clerk to advertise for loans of money to the amount of £10,000 at 3 per cent., to defray recent parliamentary charges and the cost of extending the gas-works, and also to ascertain the terms on which an insurance company would advance the money, repayable within 30 years.

It is announced from Dalkeith that the Police Commissioners, finding, on inquiry, that the gas-engine which is employed to pump water for the supply of the town does not possess sufficient surplus power to drive a dynamo, the proposal to introduce electric lighting has been abandoned. The Gas Company is not, however, to be allowed to occupy the field so peacefully as hitherto. At Monday's meeting of the Commission, Bailie Murdoch, in view of the fact that the electric light proposal had fallen through, moved a resolution to the effect that, considering the very inferior quality of gas presently supplied by the Dalkeith Gas Company, the Commissioners, as representing the public, and as being considerable consumers, would respectfully urge upon them in future to supply gas of a purer and better illuminating kind. Mr. Urquhart seconded the motion; and after some conversation it was approved—Provost Gray remarking that he thought it too strong, but would not move an amendment, as he was sure the Gas Company would give every attention to the subject.

An extraordinary general meeting of the shareholders of the Armadale Gas Company, Linlithgowshire, was held on Tuesday, to consider whether the Company, by reason of their liabilities, could continue business; and, if necessary, to pass a resolution to have the concern wound up. Mr. J. Aitken, Airdrie, who presided, said that for the last two years the Company had not been a paying one; the reason for this being bad management, and consequent loss of consumers. They had been steadily falling into debt; and this year the outlook was blacker than ever. He thought it best for them to sell out, and run no more risk. Mr. Macdonald and Mr. Brown pressed strongly for another trial of the works for a year; and urged the necessity there was for a supply of gas in the town. After much discussion, the meeting unanimously agreed that the Company be kept going for another year.

At the annual meeting, on Wednesday, of the St. Andrews Gas Company, a dividend of £2 per share was declared, and the price of gas reduced from 3s. 9d. to 3s. 7d. per 1000 cubic feet.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

The Wishaw Police Commissioners, at their monthly meeting on Monday, had a long and lively discussion on a motion to have Craigneale and adjoining portions of the burgh provided with 30 or 40 oil-lamps. When the lighting of the thoroughfares of these districts was formerly under consideration, gas was objected to on account of the expense involved. The ratepayers in these districts contribute their due share of the burghal taxation; and yet they have hitherto been denied any participation in the public lighting provided by the rates which they have been called upon to pay. The discussion was eventually brought to a close by an amendment being adopted to the effect that the Burgh Engineer be instructed to ascertain the cost of lighting the districts in question by oil and by gas. The chief difficulty in this case is that the districts are not yet provided with gas-mains; and some time ago it was estimated that the extension of the gas supply to Craigneale, &c., would cost £668 12s.

A somewhat similar question engaged the attention of the Paisley Police Board last Monday. Certain outlying districts of the town are not lighted; and the ratepayers had naturally raised complaints to the "powers that be." When moving the adoption of the Watching and Lighting Committee's minutes, Mr. Weir referred to the matter. He said that the Commissioners knew their duty to the ratepayers in connection with
